1.0 Introduction

SLR Consulting Ltd (SLR) was commissioned by Eurowind Energy Ltd to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) at the proposed Uisenis Wind Farm. The proposed wind farm ('the proposed development') is located approximately 20km south west of Stornoway, on land within the Eisgen (Eishken) Estate on the Isle of Lewis (the Site). The proposed development location is detailed on **Figure 10.1.1**: **Site Location**.

It is anticipated that the proposed development would comprise up to 25 wind turbines with associated infrastructure including access tracks, crane hardstandings, turning heads, borrow pits, substation compound and temporary construction compounds.

The purpose of this report is to consider the extent of peat and potential peat slide hazard at the Site and consider the potential impact to the proposed development, such that areas of deep peat and areas of medium to high risk of a peat slide can be avoided and/ or mitigated during the design phase.

This report presents the findings of data obtained from peat depth probing surveys conducted by SLR Consulting in August 2022, November 2022 and January 2023.

The work has been undertaken by a team of Geotechnical Engineers and Geologists, with over 10 years experience in undertaking peat assessments. The team was led by a chartered Hydrogeologist with 30 years' consultancy experience and specialising in the assessment of soils, geology and water for renewable power projects in Scotland.

The methods adopted for the assessment follow the best practice guidance[1] issued by the Scottish Government for investigation, assessment and reporting for windfarms in peat areas. Where relevant, reference is also made to guidance published by the Scottish Environment Protection Agency (SEPA) and windfarm construction good practice guidance.

1.1 Background

The importance of assessing the stability of peat deposits in relation to wind farm developments came to the fore as a result of peat failures during the construction of Derrybrien[2] Windfarm in Ireland in 2003. Although no fatalities were associated with these failures, there was a significant environmental impact. Wind farms tend to be constructed in high moorland areas which are associated with significant peat deposits (typically blanket bogs). There is a potential for peat instability to occur, particularly where deposits are in excess of 1m thick. Peat instability is influenced by many factors, including, but not limited to, peat thickness, hill slope gradient, underlying geology and subsurface hydrology.

1.2 Site Location and Description

The proposed development is located approximately 20km south west of Stornoway, on land within the Eishken Estate on the Isle of Lewis.

The proposed development is comprised of 25 wind turbines, and associated infrastructure including:

- associated turbine formations and transformers;
- hardstanding areas for erecting cranes at each turbine location;

1 Peat Landslide Hazard and Risk Assessments (Scottish Government, April 2017)
2 Lindsay, R.A. and Bragg, O., (2004), 'Windfarm and Blanket Peat, The Bog Slide of 16th October 2003 at Derrybrien, Co. Galway, Ireland'. University of East London

- upgrading of existing road and tracks;
- series of on-site access tracks connecting each turbine;
- underground cables linking the turbines to the grid connection;
- on-site substation;
- temporary construction compound(s);
- turning heads;
- meteorological masts; and
- borrow pit(s).

The layout of the proposed development is detailed on **Figure 10.1.2**: **Site Layout**.

The Site is currently accessed via an unnamed existing road (the Eishken Road) off the A859 between Balallan and Kintarvie. The road spans approximately 12.07km from the A859 to the Eishken Estate Lodge.

Ground elevations throughout the Site vary significantly, ranging from 10m Above Ordnance Datum (AOD) along the banks of Loch Eisgein and Loch Sealg to a high point of approximately 270m AOD in the north west. The centre and east of the Site are relatively flat with localised outcrops of bedrock amongst flatter expanses that allow for peat to accumulate. The west of the Site is comprised of undulating, open hillsides and towards the south of the Site, there is a steep river valley with Abhainn Cheothadail flowing east, discharging to Loch Feoir and Loch Eisgein. South of this river, there is a series of hills with elevations up to 236m AOD at Creag na Beirighe. There are flat expanses on the hilltops in the south of the Site, which allows for localised pockets of deeper peat.

The photos further below provide an overview of the of the main areas of the Site.

Photo 1-5: View looking north from the southern area of the Site at NB 30747 11925

1.3 Objectives of Report

The peat stability assessment is primarily concerned with the influence of the peat on the development of the proposed wind farm. The main objective is to assess the potential peat stability at the proposed development, identify areas of potential concern and identify mitigation measures to ensure the maintenance of peat stability before, during and after construction. All aspects of construction should be based on ensuring minimum disruption to the peat areas. The objectives have been achieved by completion of the following:

- a desk based review of available reports which include geological, hydrological and topographical information;
- Review of historic peat probing data;
- Supplementary Phase 1 Low resolution peat depth survey undertaken by SLR in August 2022 following up from the previous phases of peat probing undertaken to support Environmental Impact Assessments of previous wind farm schemes between 2006 and 2013;
    - Muaitheabhal Wind Farm (ECU ref. EC00005222);
    - Muaitheabhal Wind Farm Southern Extension (ECU ref. EC00002096);
    - Muaitheabhal Wind Farm Eastern Extension (ECU ref. EC00005223) consents);
- Phase 2 peat depth surveys, undertaken by SLR in November 2022 and then following design iterations in January 2023;
- geomorphological mapping of the Site to identify the prevailing conditions influencing the potential for, or any evidence of, active, incipient or relict peat instability, including identification of the location and photographic record, as appropriate;
- reporting on evidence of any active, incipient or relict peat instability, and the potential risk of future instability, describing the likely causes and contributory factors;
- identification of potential controls to be imposed on the Contractors for the Works to minimise the risk of peat instability occurring at the proposed development; and
- provide recommendations for further work or specific construction methodologies to suit the ground conditions at the Site to mitigate any unacceptable risk of potential peat instability.

1.4 Peat Landslide Hazard and Risk Assessment

The purpose of a PLHRA is to identify those parts of the Site that are naturally susceptible to a higher risk of instability so that they can be avoided or accommodated. It should be noted that all peat slopes have a risk of instability and the vast majority of peat slope failures occur naturally.

Construction of the proposed development would only increase the risk of peat slope instability if good geotechnical construction practice is ignored, and it is a requirement of all renewable energy developments to follow a very carefully worded and designed Construction and Environmental Management Plan (CEMP) which uses many of the recommendations of the PLHRA.

Without the guidance contained in a Construction Method Statement or CEMP, the following factors would increase the risk of instability:

- construction of access tracks;
- excavation and stockpiling for foundations;
- construction of hardstanding area; and

- blocking of natural drainage, inappropriate new drainage or drainage discharge.

It is important to note that peat instability and the impacts of any instability are not constrained by artificial Site or ownership boundaries but by topographic and geomorphologic boundaries. It is therefore important to ensure that the breadth of scope of any assessment adequately covers the areal extent of possible impact.

The risk assessment is based on ground models developed using a Geographical Information System (GIS) specifically for this Site. A numerical analysis was undertaken in which coefficients were allocated for each of the factors influencing peat stability and their impact on possible receptors. This aspect is described in greater detail in Section 6.0.

The conceptual layout of the wind turbines and access routes, the findings from the peat probing, sampling and analysis were used by the design team to optimise the wind turbine layout to avoid or mitigate areas of unacceptable peat slide risk. The layout presented in the drawings represents the final iteration of the wind turbine layout.

This system outlined above was developed in accordance with the guidelines on PLHRA by the Scottish Government (SG)[1] for the investigation, assessment, and reporting for windfarms in peat areas. The analysis and interpretation are based upon the results obtained from this process as well as previous experience and the results of case studies elsewhere. Where deviations from this guidance have occurred, this is highlighted and explained in the text.

2.0 Desk Based Review

2.1 Topographic Surveys

All of the surveys were based on 5m DTM data which was used to determine slopes across the Site and to determine slope coefficient (score) factors at each probe hole location. The Site has been characterised into slope classes and a slope plan produced to identify slope areas where potential gradients are more or less susceptible to slope failure mechanisms.

2.2 Geology

2.2.1 Soils

The principal soil type underlying the Site are peaty gleys, with mineral podzols and peat also present. The peaty gleys and podzols are drifts derived from Lewisian gneisses.

2.2.2 Superficial Geology

The British Geological Survey (BGS) indicates the presence of limited superficial cover with a small localised area of Glacial Till mapped within the south western corner of the Site and a small area of peat mapped in the western area of the Site. In areas of higher elevation and steeper gradients, the BGS mapping indicates no superficial deposits being present and shallow bedrock at surface throughout the Site. The carbon and peatland map 2016[3] provides useful information regarding peat and soil coverage within the site boundary.

Peat is present throughout the majority of the Site. The Site is comprised of peaty soils and localised areas of deep peat. Published priority peatland mapping by NatureScot indicates that most of the Site is located within Class 1 and Class 2 peatland which is considered to be of high conservation value. Based on observations from recent Site visits blanket bog was present with peat identified as being pseudo fibrous to amorphous in the flatter areas of the Site with more fibrous to pseudo fibrous peat on the slopes.

The bedrock surface dominates the topography throughout the Site often confines areas of peat due to the size, dip and shape end extensive outcropping bedrock. This is a particularly dominant feature in the south of the Site where there are flatter expanses with peat situated on hilltops, confined by the outcropping bedrock on the hillsides and slopes. In flatter areas in the centre of the Site, the peat is situated in confined bowls between outcropping bedrock.

The superficial geology of the Site is detailed in **Figure 10.1.3**.

2.2.3 Bedrock Geology

The BGS indicates that the Site is predominantly underlain by the Outer Hebrides Thrust Zone Mylonites Complex. This formation is comprised of Precambrian (4000 to 541Ma) metamorphic fault rocks including mylonites, protocataclasite, cataclasite and pseudotachylite. Fault rocks consist of compressed fragments of rock material produced by the grinding and brittle deformation forces associated with fault activity.

A small area within the north of the site is underlain by Precambrian Amphibolite which is a coarse-grained metamorphic rock belonging to the Lewisian Complex. Some of the access tracks and turbines, T5 and T8, are proposed for construction in this area. In addition, there are localised areas alongside the existing access track that are mapped as Gneiss belonging to the Lewisian Complex.

3 NatureScot, (2016) Carbon and Peatland 2016 map. Available from: http://map.environment.gov.scot/soil_maps/ Scottish Government, 2016

There are several inferred faults present within the Site boundary. There is a major thrust fault in the west of the Site trending north to southeast. There is another major fault in the south of the Site trending east to west through Loch Eisgein and the river valley where Abhainn Cheothadail is present. In addition, there are two thrust faults present in the east and south of the Site, trending north east - south west that appear to be offset by the major fault in the south.

Based on recent Site observations from August 2022, November 2022 and January 2023, the bedrock encountered on-site is predominantly coarse grained and strong.

The bedrock geology of the Site is detailed in **Figure 10.1.4**. Details of the geological units present on-site and immediately adjacent to Site are detailed in **Table 2-1**.

Table 2-1: Bedrock Geology Summary

Age		Stratigraphic Group	Unit	Description
Precambrian	Proterozoic (541 to 2500Ma) to Archaean (2500 to 4000Ma)	Uig Hills – Harris Igneous Complex	Granite	Coarse-grained intrusive igneous rock
		Outer Hebrides Thrust Zone Mylonites Complex	Mylonite	Fine-grained metamorphic fault rock with reduced grain size due to dynamic recrystallisation of the constituent minerals.
		Outer Hebrides Thrust Zone Mylonites Complex	Cataclasite	Fault-related metamorphic rock that maintained primary cohesion during deformation, with matrix comprising greater than 10% of total rock mass
		Outer Hebrides Thrust Zone Mylonites Complex	Pseudotachylite	Very fine-grained, glassy fault rock
		Lewisian Complex	Amphibolite	Coarse-grained metamorphic rock containing amphibole.
		Outer Hebrides Thrust Zone Mylonites Complex	Protocataclasite	Fault-related granular metamorphic rock that maintained primary cohesion during deformation, with matrix comprising 10-50% of total rock mass

2.2.4 Mining and Quarrying

Following review of publicly available records, there is no history of coal or commercial mineral extraction within the site boundary and immediate area. BGS Geoindex indicates that there are small borrow pits present alongside the existing road within the Site boundary.

2.3 Hydrology

The Site exhibits a dense network of surface water features with numerous water courses and lochs noted throughout the area.

The majority of the Site is located within the surface water catchment of Loch Sealg, in particular the Abhainn Cheothadail sub catchment. The Abhainn Cheothadail flows generally eastward through the centre of the Site before discharging into Loch Sealg near Eisgein (Eishken) which is situated in the south east of the Site. The Abhainn Gleann Airighan Domhnall, another catchment of Loch Shell, is situated in the south west heading eastward before discharging into Loch Shell along the southern boundary of the Site.

The north eastern extent of the proposed development is located within the surface water catchment of the Abhainn Ghlas which is part of the larger Seaforth River catchment. The Abhainn Glas generally flows northwards before discharging into the Abhainn Ghleann Quirn approximately 1km north of the Site. The Seaforth River flows westwards within the centre of the Site before discharging into Loch Sgiobacleit approximately 100m south of the proposed access track.

The central section of the proposed access track also drains to the Loch Seaford whilst the northern extent of the access track is located within the catchment of the Abhainn Mhor, which drains to the Loch Erisort approximately 1km north west of the proposed access point.

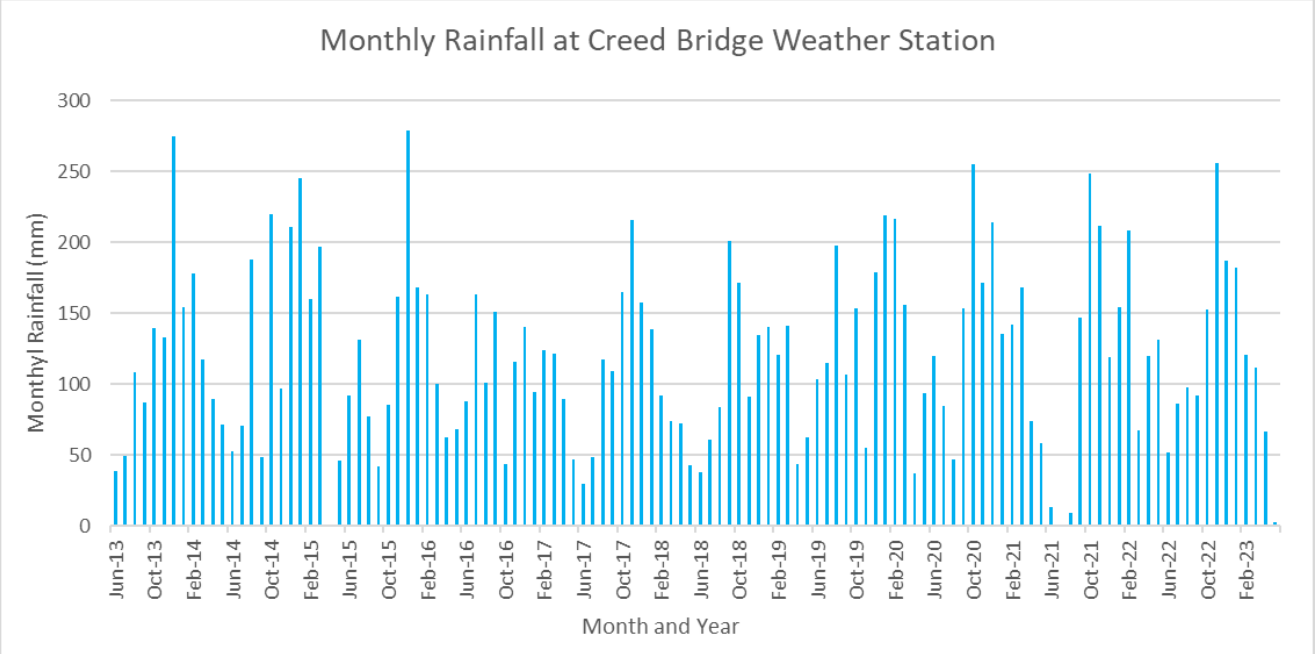
2.4 Hydrogeology

The solid geology underlying the Site is classified as fault zone rocks and a low productivity aquifer, where mylonitic rock and fault breccias yield small amounts of groundwater resulting in flow occurring predominantly through fractures and discontinuities. Small amounts of groundwater may be present within near surface fractures and weathered rock and from springs locally.

2.5 Rainfall

Periods of intense heavy rainfall are often seen as triggers for instability events. Rainfall data from the closest SEPA weather station shows the average monthly rainfall in the region from June 2013 until April 2023. The most average rainfall for April 2023 was 64.4mm.

Chart 2-1: Monthly rainfall data from Creed Bridge Station located north of the Site near Stornoway



2.6 Geomorphology

The Site is generally characterised by flat, low-lying areas in the centre and east of the Site with local, minor variations in topography. The north, west and south of the Site are predominantly higher elevation with steep slopes and occasional flatter expanses.

2.6.1 Aerial Photography Interpretation and Site Observations

The aerial photographs were used in conjunction with the Site DTM data to identify the major geomorphological features such as the breaks of slope and landslips. These were inspected where identified during Site visits when more detailed assessment of the Site was undertaken.

Aerial photography using google earth was reviewed dating back to 1985 with images from 2005, 2012, 2013, 2019 and 2021 also used. Interpretation of available aerial photographs was undertaken to assess and identify evidence of historic peat instability. The photographs were examined using various techniques to highlight features of interest, such as:

- possible extension and/or compression features;
- areas of historic failure scars and debris;
- evidence of peat creep;
- areas with apparently poor drainage;
- areas with concentrations of surface drainage networks;
- steeply incised stream cuttings within peat deposits; and
- areas with peat drift recorded on steep slopes.

Selected photographs are used to illustrate the mapping and interpretation from within the Site.

Erosional Features - Peat Haggs

Peat haggs are absent in the flatter northern areas of the Site. There are small areas of hagging predominantly in the east, south and south west of the Site on flatter lying areas on the upper slopes.

The main types of erosion encountered on the Site were gully erosion, shown in **Photo 2-1** and in **Photo 2-2** below with the areas of gully erosion on the higher upland areas in the south west also impacted by wind erosion.

Photo 2-1: Gully erosion in southwest of the Site

Photo 2-2: Gully erosion in southwest of the Site

Drainage

Natural

Freshwater drainage across the site is characterised by a network of streams, rivers and lochs. The large majority of drainage channels were located in the centre, north and south of the Site. The drainage in the northern area of the site drains to the south into the Abhainn Cheothadail.

There are frequent minor lochs and lochans situated throughout the area, predominantly in the centre, north and east of the Site within the flatter expanses of the Site. These lochs typically drain to the south and south east into Loch Eisgein.

The minor lochans in the southern area of the Site in the area around T20 and T24 drain to the south into Loch Sealg.

The only marine loch within the Site boundary is Loch Sealg, situated in the south east of the Site.

The largest river within the Site boundary is Abhainn Cheothadail located in the south of the Site and is shown in **Photo 1-5**, which is fed by Loch na Beirighe and multiple streams located on the northern and southern flanks of the river valley. This river flows east, discharging into Loch Feoir, Loch Eishken and ultimately Loch Sealg.

Artificial Drainage

There are areas of artificial drainage across the east, centre and south of the Site, as shown in the geomorphology plan provided in **Figure 10.1.5**. These are linear channels cut into the peat and soil on the Site and are shown in detailed in **Photo 2-3** further below.

Forestry

No forestry was observed from the aerial photos within the development area which is consistent with on-site observations.

Bedrock

The Ordnance Survey maps show frequent outcrops on-site in areas of undulating terrain and areas of higher elevation and the main expanses are shown in the geomorphology plan provided in **Figure 10.1.5** This is also confirmed by the Site visit where exposed bedrock was frequently observed and recorded.

Extension/Compression Features

There was minimal evidence visible in the aerial photographs of any extension or compression features in the peat within the Site boundary. It was not possible to identify evidence of any significant historic peat failures or slides on the development site from the aerial photographs.

However, the site walkovers identified an area in the south of the Site that recorded a landslide. Based on further investigation of this area, review of aerial imagery, limited peat depth and the steep slope angle, it was concluded that this landslide is likely associated with failure at the substrate and bedrock interface.

Whilst indications of peat erosion features were identified no evidence of Peat Landslide was observed on Site.

The slide present in the southern area of the Site is located to the south of the Abhainn Cheothadail river, on the northern flank of the hills facing inward into the valley, approximate national grid reference: NB 31152 12179. The debris slide is approximately 80m in length and 10m wide at the top. No infrastructure is planned in this immediate area of the Site and the closest proposed infrastructure is T19, approximately 190m south east of the debris slide. Photographs showing the slide are displayed below in **Photo 2-3** and **2-4**.

In addition, outwith the Site boundary, there are areas of instability that have been identified from aerial photography that are in relatively close proximity to the Site.

There is a debris slide present on the north east facing slope of Creag na Beirighe, which is approximately 52m from the south west Site boundary, with approximate national grid reference: NB 29217 11919. The debris slide is approximately 30m in length and 11m wide. This type of instability is known as soil creep, which occurs from the gradual movement of superficial depositions due to overland surface water flow, gravity, and freeze-thaw action. OS Imagery and aerial imagery showing the slide and slide location is displayed below in **Photos 2-5** and **2-6.**

There is a potential peat slide present on the south west facing slope of Beanna Mor, which is approximately 610m from the south west extent of the Site boundary, with approximate national grid reference: NB 28556 10073. The slide is approximately 14m in length and 10m wide. This white scar is distinctive in comparison to the surrounding landscape and erosional features where underlying mineral soils are exposed. This area of instability is likely a peat slide due to the characteristic shape and the absence of surrounding run-off material and extensive adjacent erosion. Aerial imagery showing the slide is displayed below in **Photo 2-6**.

Photo 2-2: View of local instability facing south from NGR NB 30952 12590

Photo 2-3: View of local instability facing southeast from NGR NB 30792 12436

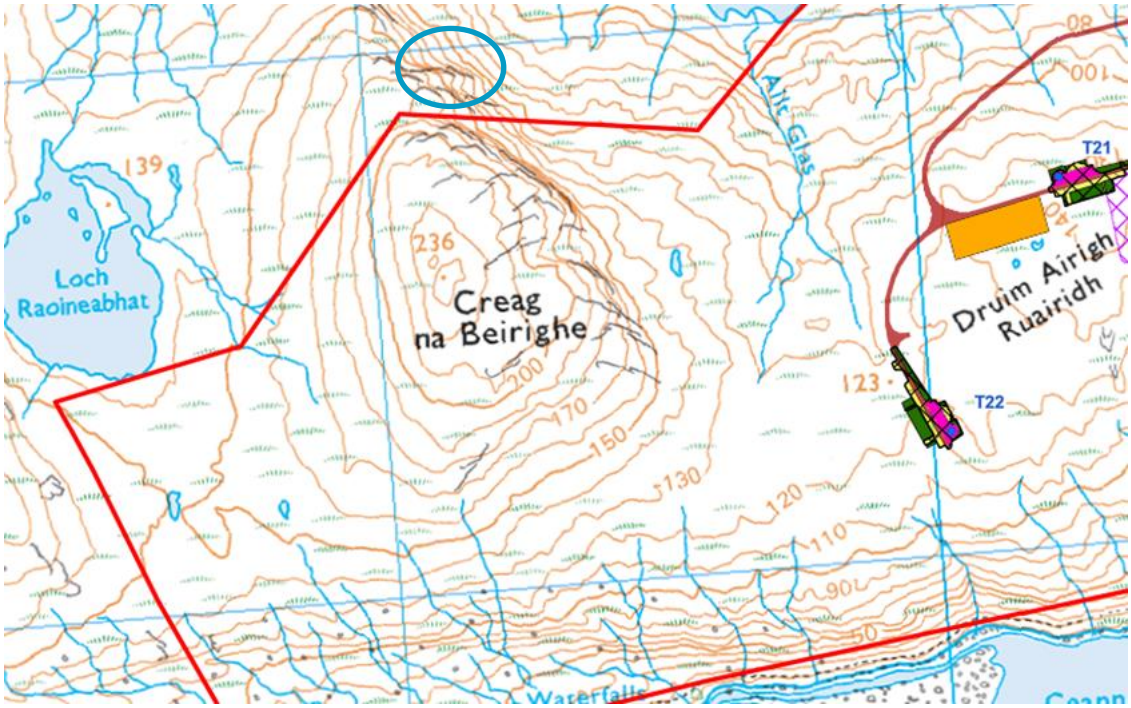

Photo 2-5: Potential Debris Slide identified from aerial photography at NGR NB 29217 11919

Photo 2-6: Potential peat slide identified from aerial photography at NGR NB 28556 10073

2.7 Site Observations

From observation during the site walkover Peat is typically present as blanket bog throughout flatter expanses of the Site, predominantly in the centre, east and flatter expanses of the southern areas of the Site. Peat also typically accumulates in topographic depressions between areas of outcropping bedrock. The peat present in the flatter areas of the Site is generally thick peat and more amorphous. Peat situated on slopes and hillsides is generally thin peat and more fibrous.

Outcropping bedrock at surface is a dominant feature throughout the Site. Exposed bedrock is present on hillsides, slopes, and areas of higher elevation throughout the Site. In addition, there are frequent exposures in flatter expanses of the Site where outcropping bedrock is present creating a hummocky landscape.

There are rare exposures of superficial geology throughout the Site, displayed below in **Photos 2-7**, **2-8** and **2-9**. Although not officially mapped by BGS, this has been identified as glacial till comprising sand and gravel.

Photo 2-7: Exposure of glacial till at NGR 31248 14533

Photo 2-8: Exposure of glacial till at NGR NB 32469 14344

Photo 2-9: Exposure of glacial till at NGR NB 32483 14340

Peat erosion features are present on-site as hagging on the higher slopes in the east, south and south west of the Site although this was not evidenced within the central flatter areas of the Site. Erosional features were present and identified as resulting primarily from gully erosion with some wind erosion.

Other geomorphologic features evident from the Site reconnaissance and aerial photographs included:

- peat flushes;
- lochs and lochans;
- deeply incised valleys;
- small streams;
- standing water and ponding; and
- ridges, rock outcrops and various glacial features.

A summary of the geomorphology of the Site is included in **Figure 10.1.5** with the main features discussed further below.

3.0 Peat Instability

This section reviews the nature of peat and how current and past activities can influence stability. The factors which are likely to influence the potential for peat instability are:

- significant peat depths over impermeable bedrock or minimal soil;
- the presence of slope gradients greater than 4° (approximately) and general topography;
- natural drainage paths;
- evidence of past failures, including soil creep;
- drainage features at the base of slopes which could lead to undercutting;
- forestry plantations and artificial drainage; and
- recent climate patterns.

It should be noted that peat instability is not a recent phenomenon and there is documentary evidence of peat landslides dating back over 500 years[4]. Many landslides that involve peat have no human interference that could be considered as a trigger and this should be borne in mind when considering the susceptibility of a site to potential instability.

3.1 Background Information Regarding Peat

Peat is found in extensive areas in the upland and lowland regions of the UK and is defined as the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of water logging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat 'grows' in-situ.

Peat is characterised by low density, high moisture content, high compressibility and low shear strength, all of which are related to the degree of decomposition and hence residual plant fabric and structure. To some extent, it is this structure that affects the retention or expulsion of water in the system and differentiates one peat from another.

Lindsay[5] defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the west coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominantly supplied with water and nutrients in the form of precipitation. Blanket peat is usually considered to be hydrologically disconnected from the underlying mineral layer.

There are two distinct layers within a peat bog, the upper acrotelm and the lower catotelm. The acrotelm is the fibrous surface to the peat bog[6], typically less than 0.5m thick; which exists between the growing bog surface and the lowest position of the water table in dry summers. Below this are various stages of decomposition of the vegetation as it slowly becomes assimilated into the body of the peat.

For geotechnical purposes the degree of decomposition (humification) can be estimated in the field by applying the 'squeezing test' proposed by von Post and Grunland[7] (1926). The humification value ranges from H1 (no

decomposition) to H10 (highly decomposed). The extended system set out by Hobbs[8] provides a means of correlating the types of peat with their physical, chemical and structural properties.

The relative position of the water table within the peat controls the balance between accumulation and decomposition and therefore its stability, hence artificial adjustment of the water table by drainage requires careful consideration.

3.1.1 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the physical characteristic that provides stability and coherence to a body of soil. For mineral soils such as clays or sands, such strength is variously given by an inter-particle friction value and cohesion. Depending whether the mineral soil is predominantly cohesive (clay) or non-cohesive (sand) governs which of the components of strength control the behaviour of the soil.

For peat soils, where the major constituent is organic and there is likely to be little or no mineral component, the geotechnical definition of shear strength does not strictly apply. At present there is no real alternative method for defining the shear strength of peat, therefore the geotechnical definition is generally adopted, in the knowledge that it should be used with great caution.

As noted previously, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and vegetable fibres. These roots and fibres impart a significant tensile shear strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is, in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become more rotted. However, the loss in strength due to decomposition is off-set to a limited degree, by a gain in strength due to the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and the thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading. Typical values of shear strength from hand shear vanes would be in the range 10-60 kilopascal (kPa) although values over 100kPa have been recorded in peat elsewhere. The higher strengths are almost certainly the influence of roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted, however, that any quotation of shear strength for peat should be treated with extreme caution.

3.1.2 Peat Stability – Factors to be Considered

There is considerable observational information relating to debris and peat flows although the actual mechanisms involved in peat instability are not fully understood. The main influences on slope stability are geological, geotechnical, geomorphic, hydrological, topographic, climatic, agricultural and human influences such as drainage and construction activity. Peat is affected to a degree by changes in any of the above list and it is vital to appreciate that changes to the existing equilibrium would affect the level of slope stability during construction and operation of the proposed development.

Some of the contributory factors to peat instability are summarised below:

- the geographical limits which could be affected by potential instability are not confined to the artificial boundaries imposed by land ownership; landslip occurring above a site could affect the site and property down slope or downstream of the site for several kilometres;

8 Hobbs, N.B., (1986), 'Mire morphology and the properties and behaviour of some British and foreign peats.' Quarterly Journal of Engineering Geology, London, 19, 7-80.

- agriculture and grazing have a substantial effect on peat areas and this can be compounded in areas that have been managed to improve grazing. Grazing compacts the peat surface reducing the rainwater infiltration and the additional nutrients change the ecological balance of the original peat bog. Agricultural management can include surface drainage and periodic burning, both of which can leave the surface of the peat bare for a period of time resulting in temporary desiccation of the surface. Subsequent wetting of the peat and resumption of peat accumulation results in the former desiccated and possibly ash covered surface being incorporated into the body of the peat which introduces a weak discontinuity in the profile; this in turn becomes another unknown factor in the stability assessment;
- forestry has a substantial effect on slope stability particularly in the early stages as the creation of a forest involves disruption of the natural equilibrium and drainage of the slopes and the installation of artificial drains by deep ploughing. The construction of access tracks further disrupts the drainage and concentrates groundwater flow into narrow, fast flowing erosive streams. The work by Winter *el al* [9] noted that forest tracks can act to retard or concentrate the down slope flow of water and thus aid its penetration into the slope below. Such a mechanism has been observed at a number of recent landslips that have affected the road network in Scotland;
- natural Drainage – some of the precipitation falling onto a natural upland peat bog would be absorbed into the low permeability catotelm peat. However, most of the water would run-off as sheet flow through upper, high permeability acrotelm. Thus, the water is transmitted to the lower slopes in a reasonably controlled manner through a range of interconnections that operate at different scales and speed. Failure to understand this and to disrupt the transmission process for the groundwater could result in instability; and
- artificial Drainage - Where agricultural drainage has been used to improve the quality of the grazing or to promote forestry it reduces the overall volume of water entering the bog and transfers this water to the edges more rapidly. This can result in ditches and streams becoming enlarged, causing increased erosion and a greater silt burden in the stream water.

3.2 Peat Mass Stability

The principal surface indicator of peat slide potential is cracking of the peat land surface, and it is the identification of crack patterns in the field and the attendant causes of the cracking that is fundamental to a peat stability assessment.

Sites that have exhibited natural instability in the past are likely to be more susceptible to future instability during and following construction of a renewable energy development, therefore it is important to identify such instability as part of the Peat Stability Assessment.

3.2.1 Types of Failure

The result of instability in peat is the down-slope mass movement of the material; there are a number of definitions of peat instability which are used to characterise the type of failure. A brief description is given below:

- Bog Bursts or Bog Flows – the emergence of a fluid form of well humified, amorphous peat from the surface of a bog, followed by the settling of the residual peat, in-situ [10];

[9] Winter, M.R., Macgregor, F. and Shackman, L. (2005a), 'Scottish tracks networks landslide study' Trunk tracks: network management division, published report series. The Scottish Government.
[10] Dykes, A.P and Kirk, K.J., (2001), 'Initiation of a multiple peat slide on Cuilcagh Mountain, Northern Ireland.' Earth Surface Processes and Landforms, 26, 395-408.

- Peat Slides – the failure of the peat at or below the peat/ substratum interface leading to translational sliding of detached blocks of surface vegetation together with the whole underlying peat stratum[10]; and
- Bog Slide – an intermediate form of instability where failure occurs on a surface within the peat mass with rafts of surface vegetation being carried by the movement of a mass of liquid peat.

3.2.2 Bog Bursts

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failure are given below:

- peat thickness in excess of 1.5m with no upper limit;
- shallow gradients, generally within the range of 2 to 10°, peat thicker than 1.5m is generally not observed on slopes steeper than 10°, also moisture content is generally reduced on steeper slopes due to drainage);
- ground which is annually waterlogged to within the upper 1m below ground level, (the groundwater level may rise above this but rarely falls below)[11];
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

3.2.3 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate.

The factors generally considered to influence susceptibility to peat slide failures are listed below:

- peat depth up to 2m;
- slope gradients between 5° and 15°;
- natural or artificial drainage cut into the surrounding peat landscape;
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

It is noted that some of the factors causing instability are common to both bog bursts and peat slides.

The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

[11] Crisp, D.T., Dawes, M. & Welch, D. (1964), 'A Pennine Peat Slide', The Geographical Journal, Vol 130, No4, pp519-524.

3.2.4 Bog Slides

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelmic and catotelmic layer.

3.2.5 Natural Instability

The stability of a peat mass is maintained by a complex interrelationship of many factors, some of which may not be immediately obvious. Key factors include sloping rock head and proximity to a water body. Rainfall often acts as the trigger after the slope has already been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming will be a greater frequency of extreme weather, intense storms being one element.

4.0 Site Work

4.1 Peat Depth Survey

Peat depth surveys have been undertaken across a number of phases by SLR and other parties. Existing peat probe data was carried out in support of the 2004 Muaitheabhal Wind Farm application, the 2010 Muaitheabhal Wind Farm Eastern Extension application, and the 2013 Muaitheabhal Wind Farm Southern Extension application (all now consented). This Peat Landslide Hazard Risk Assessment uses the peat depth data collected by SLR and also the peat depth data collected in support of the Muaitheabhal Wind Farm applications.

The SLR surveys were carried out followed best practice guidance for developments on peatland[12,13]. Low resolution Phase 1 peat probing resulted in probing on a 100m grid to allow for initial assessment of the Site which was used in preliminary site layout designs and supplemented by utilising historic peat probing data available for the Site. A further two phases of high resolution probing saw detailed probing undertaken across the proposed layout, focussing on access tracks, turbine locations and other site infrastructure. Existing tracks proposed for upgrade were probed on 100m spacings with new site tracks typically probed at 50m spacings. Probing density within the main areas of permanent infrastructure was typically probed on a 10m grid with allowance for micrositing.

Peat is generally defined as an organic soil in excess of 0.5m, if the soil is less than 0.5m, then it is considered peaty soil. The peat was found to vary across the site in terms of thickness and coverage.

Thin peat was classed as being 0.5m to 1.5m thick, with deposits in excess of this being classed as thick peat. The thickness ranges used were intended to reflect the probability of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded less than 0.5m thick, this has been considered to be an organic/peaty soil rather than peat.

Where surveys were undertaken by SLR, the thickness of the peat was assessed using a graduated peat probe, approximately 6mm diameter and capable of probing depths of up to 10m. This was pushed vertically into the peat to refusal and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as ±2m, which was considered sufficiently accurate for this survey. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the 'feel' of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- solid and abrupt refusal – rock;
- solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- rapid and firm refusal – clay; or
- gradual refusal – dense peat or soft clay.

Where surveys were undertaken by SLR, an assessment of the substrate was made and recorded at each probe hole. For use within this assessment, engineering judgement has been used to assess the substate at probes undertaken by other parties.

[12] Scottish Renewables & SEPA (2012) 'Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste'.
[13] Scottish Natural Heritage (SNH), SEPA, Scottish Government & James Hutton Institute. (2014)' Peat Survey Guidance; Developments on Peatland: Site Surveys'.

The relative stiffness of the peat was also assessed from the resistance to penetration of the probe and to the effort required to extract the probes (retrieval of the probe was often impossible for one person). In all instances refusal was met on obstructions allowing identification of subsurface geology.

4.2 Peat Depth Survey Results

The results from all probing exercises listed above in Section 4.1 are detailed in the following sections and the peat depths identified on-site are shown in **Figure 10.1.6** and **Figure 10.1.7**. All probing data is provided in **Annex A**. The Inverse Distance Weighting (IDW) method of interpolation was used to develop the peat models.

The peat was found to vary across the Site in terms of thickness and coverage. The slopes on-site are detailed in **Figure 10.1.8**. When viewed in conjunction with **Figure 10.1.6** and **Figure 10.1.7**, it is evident that the larger areal extents of deep peat are generally limited to flat expanses that mimic the topographic flat lying areas. There were also very localised areas of deep peat on-site, defined by lower gradients topography and undulating bedrock. Peat coverage was extensive throughout the centre of the site and in localised areas in the north, east and south of the Site.

Accumulations of peat up to 0.5m thick are considered to be too thin to be classified as true peat deposits and are often classified as organic soils or peaty soils.

A total of 18,241 peat probes were undertaken across all survey phases, with the results summarised in **Table 4-1** below.

Table 4-1: Peat Probing Data

Peat Thickness (m)	No. of Probes	Percentage (of total probes undertaken on-site)
0 (no peat)	4,401	24.1
0.01 – 0.49 (peaty soil)	6,164	33.8
0.50 – 0.99	4,323	23.7
1.00 – 1.49	1,604	8.8
1.50 – 1.99	817	4.5
2.00 – 2.49	388	2.1
2.50 – 2.99	266	1.5
3.00 – 3.49	148	0.8
3.50 – 3.99	58	0.3
> 4.0	72	0.4

4.3 Peat Condition

Peat is described using the von Post[7] classification. Peat samples were collected by SLR in November 2022, using a peat auger and used to inform interpretations of the peat condition and underlying substrate.

Based on Site interpretations from probing and peat core samples, the peat within the site boundary is predominantly amorphous and heavily degraded. There are some localised deposits of shallow peat that generally comprise fibrous to pseudo-fibrous layers, whilst areas of thicker peat are predominantly pseudo-fibrous to amorphous layers.

Based on field descriptions at augering points, most of the shallow peat would be classified as between H5 in the von Post classification, showing moderate decomposition with considerable amorphous material. The deeper

peat, in excess of 1.0m is more decomposed and generally between H7 and H10. Peat Core logs and photographs are presented within **Annex B**.

4.4 Substrate

Where possible, in the SLR investigation, an assessment of the substrate was made, as described previously. From the evidence of the probing and sampling where available, the substrate falls into one of two principal categories:

- granular (sand and/or gravel/weathered rock), of glacial origin and occasionally interbedded with silty sands;
- rock, no rock samples were recovered from the probe locations although where exposed, the rock is observed to comprise metamorphic rock of the Lewisian Complex;
- the bedding dip and discontinuity spacing could not be determined at this stage but evidence from outcrops confirms the metamorphic rocks are folded and exhibit variable bedding orientations and should be subject to further investigation for the design of the turbine foundations; and
- limited cohesive horizons were interpreted by the probing, however evidence from the site walkovers did not encounter cohesive soils on site. It is likely that any cohesive material is weathered silty material at the top of the weathered glacial material.

5.0 Slope Stability/Ground Conditions

The stability of slopes is dependent upon the shear strength of the soil to resist the disturbing forces due to the weight of the soil, the effects of the groundwater and other disturbing influencing forces.

The level of stability of a slope is normally assessed by reference to the factor of safety which is expressed, numerically, as the degree of confidence that exists, for a given set of conditions, against a particular failure mechanism occurring. It is commonly expressed as the ratio of the load or action which would cause failure against the actual load or actions likely to be applied during service. This is readily determined for some types of analysis (e.g. limit equilibrium slope stability analyses).

5.1 Shear Strength

The strength of the peat in the upper acrotelm is significantly influenced by the root and fibres that are abundant in this layer. There are many influences on the stability of the peat and observing or measuring high shear strength should not be used to assume a high degree of stability.

5.2 Stability Risk Assessment

It is apparent that the stability of peat is complex and the numerous inter-relationships that affect the stability are not fully understood.

The problem with a quantitative assessment is that it requires a numerical input and the analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide and that a qualitative assessment of stability should be used to provide the final recommendations.

A stability risk assessment was undertaken to evaluate the risk of instability occurring associated with the construction of the turbine bases, infrastructure, and access tracks at the development.

6.0 Peat Landslide Hazard and Risk Assessment

A preliminary peat risk assessment has been undertaken for the Site. Previous peat depth survey data Following three phases of peat probing, a Site visit by an experienced SLR geotechnical engineer, and appraisal of the data, the potential for a peat slide occurring at the Site was initially assessed as medium, this was based on the fact that:

- although there are significant thicknesses of peat present on-site, the wind turbines and ancillary infrastructure has generally avoided the thickest areas of peat;
- the peat morphology is typically characterised by peat filled hollows in bedrock;
- limited granular glacial substrate was present over the site with bedrock predominant;
- limited evidence of historical or recent peat landslide activity at the Site;
- steep gradients (>8^0) where infrastructure overlying peat are proposed; and
- conclusions of a detailed walkover and results from probing.

Where areas of medium and high risk are identified, further assessment has been undertaken.

To further quantify this initial assessment, analysis of the terrain at Site utilising GIS has been undertaken to analyse slopes and gradients, as shown on **Figure 10.1.8**. The Site specific slope data has been combined with site specific peat depth data and using Scottish Government Guidance[1] for the assessment of the risk of instability in peat, an assessment of peat slide risk has been completed.

The method of risk and hazard assessment has been developed with reference to the Scottish Government Guidance[1]. Key factors which may have an effect on the stability of the peat deposits have been identified leading to an assessment of the RISK of instability. The potential impact of any instability, the HAZARD, was then considered for identified potential receptors. Scores were attributed to the key factors that have the greatest influence on peat stability. Risk scores were determined, which, when combined with an assessment of vulnerability of potential targets, were developed into an assessment of the hazard.

In order to differentiate between risk and hazard, the following nomenclature has been adopted in **Table 6-1**.

Table 6-1: Risk versus Hazard

Risk	Hazard
Negligible	Insignificant
Low	Significant
Medium	Substantial
High	Serious

This section outlines the approach taken and the scores allocated for various factors relevant to peat stability.

At this stage, the objective is to determine the peat areas that would have an effect on the proposed development and to set out the mitigation that could be adopted and incorporated into the proposed development to ensure that due cognisance is taken in this regard.

The level of slope is normally assessed by reference to the factor of safety which is expressed, numerically, as the degree of confidence that exists, for a given set of conditions, against a particular failure mechanism occurring. It is commonly expressed as the ratio of the load or action which would cause failure against the actual load or actions likely to be applied during service. This is readily determined for some types of analysis (e.g. limit

equilibrium slope stability analyses). The following sections present a brief discussion on some of the issues relating to stability and risk assessment.

The stability of peat is a complex subject and there are numerous inter-relationships that affect the stability.

A quantitative assessment requires a numerical input and such an analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide and a qualitative assessment of stability should be used to inform the final recommendations.

The characteristics of the peat failure phenomena have been incorporated in a stability risk assessment to evaluate the risk of instability occurring within the peat areas. The main factors controlling the stability of the peat mass are the surface gradients, the depth and condition of the peat at each location and the type of substrate.

The natural moisture content and undrained shear strength of the peat are important; however, it is generally accepted that where present, the peat would be saturated and have a very low strength. It is believed to be unrealistic to rely on specific values of shear strength to maintain stability when back analysis of failed slopes indicates that there is often a significant discrepancy between measured strength in peat and stability. Shear strength has been assumed to be constant and worst case, throughout this assessment. It has also been assumed, as a worst case, that the groundwater level is coincident with the ground surface.

The key factors identified as being critical to stability and the development of a risk rating system is:

- A – Slope gradient;
- B – Peat thickness;
- C – Substrate type or condition; and
- D – Historic instability.

The risk scores are multiplied together to generate a risk rating which is a measure of the likelihood of peat instability.

6.1 Slope Gradients

The slope gradients were assessed by reference to the mapping and particularly the DTM which was used to generate a gradient map (**Figure 10.1.8**), from which the gradient at each probe location could be determined and input into the risk rating spread sheet (**Annex A**). The gradient quoted at each location was based on the average gradient over a 5m grid. Significant effort has gone into avoiding areas of deep peat and reducing slopes along routes and at wind turbine bases and positioning infrastructure on flat areas. **Table 6-2** gives the coefficients applied to the slope gradient categories.

Table 6-2: Coefficients for Slope Gradients

Slope Angle (°)	Slope Angle Coefficients
Slope $<2^0$	1
$2^0 \leq$ Slope $<4^0$	2
$4^0 \leq$ Slope $<8^0$	4
$8^0 \leq$ Slope $<12^0$	6
$>12^o$ Slope	8

Coefficients for slope gradient have been assigned to ensure the potential for both peat slides (gradients of 4-15^0) and bog slides (gradients of 2-10^0) are addressed.

By simple inspection it is clear that steeper slopes pose a greater risk of instability than shallow gradients. Therefore, a graduated gradient scale from 0^0 to $>12^0$ (the practical maximum gradient on which peat is commonly observed) has been applied.

6.2 Peat Thickness and Ground Conditions

The ground conditions were assessed by using peat depths recorded during peat probing. Thin peat was classed as being 0.5m to 1.5m thick, with deposits in excess of this being classed as thick. The thickness ranges used are intended to reflect the risk of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded peat less than 0.5m thick, this has been considered to be an organic soil rather than peat. **Table 6-3** gives the coefficients applied to the various ground conditions.

In addition to peat thickness, the presence of existing landslip debris or indicators of meta-stable conditions such as tension cracks or slumping in the peat suggest the material is likely to become even less stable should the existing ground conditions change. Where evidence of historical slips, collapses, creep or flows is seen, a separate coefficient has been applied. No evidence of peat slides were noted within the Site boundary.

Table 6-3: Coefficients for Peat Thickness and Ground Conditions

Ground Conditions	Ground Condition Coefficients
Peaty or organic soil (<0.5m)	1
Thin Peat (0.5 – 1.5m)	2
Thick Peat (>1.5m)	3*
Slips /collapses / creep / flows	8

***Note that thicker peat generally occurs in areas of shallow gradients and records indicate that thick peat does not generally occur on the steeper gradients.**

6.3 Substrate

As noted above, most failures in thin peat layers occur at the interface with the underlying substrate; the nature of the substrate has a very large influence on the probable level of stability.

Where sand and/or gravel (derived from glacial till) form the substrate, the effective strength of the interface can be considered to be good with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface. Further factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

Where clay forms the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear strength parameters. The result is that potential shearing could occur either in the peat, on the interface or in the clay; all three possibilities have been documented in the past.

A rock substrate provides a high strength stratum, however, the rock surface can be smooth, and, depending on the dip orientation of the strata, it can provide a very weak interface. For these reasons, at this stage, a rock interface has been given the same risk rating as clay. **Table 6-4** gives the coefficients applied to the various substrate categories.

Table 6-1: Coefficients for Substrate

Substrate Conditions	Substrate Coefficients
Granular	1
Cohesive	2
Rock	2
Not proven	3
Slip material (Existing materials)	5

If the overall thickness of the peat had not been proven, the risk associated with the significant thickness and the unknown substrate would have been given a high rating to accommodate the unknown factors.

6.4 Risk Rating

The probability of a peat landslide rating coefficient (score) was derived by multiplying the coefficients for the four key factors (with historic instability as 1) identified in the above sections together to produce a risk rating which is a measure of the likelihood of peat instability, and this enables potential areas of concern to be highlighted.

For the stability risk assessment, the following Probability of a Peat Landslide classes were applied as shown in **Table 6-5.**

Table 6-5: Probability of Peat Landslide

Risk Rating Coefficient	Potential Stability Risk (Pre-Mitigation)	Action
<5	Negligible	No mitigation action required.
5 - <15	Low	As for negligible condition plus development of a site-specific construction and management plan for peat areas.
15 - <31	Medium	As for Low condition plus may require mitigation to improve site conditions.
31-50	High	Unacceptable level of risk, the area should be avoided. If unavoidable, detailed investigation and quantitative assessment required to determine stability and sensitivity to minor changes in strength and groundwater regime combined with long term monitoring.
>51	Very High	Unacceptable level of risk, the area should be avoided.

The rating system outlined above differs slightly from that proposed in the Scottish Government Guidance[1] as the system adopted here incorporates three inputs compared to two in the guidance, with the potential impact of substrate added in this section.

The table of results; included in **Annex A** shows that 18,241 probe locations were identified within the extent of the Digital Terrain Model, peat (>0.5m) was present at 7,676 locations. The stability risk rating identified the following:

- Negligible risk at 1,554 (9%) probe locations;
- Low risk at 5,289 (29%) locations;
- Medium risk at 5,286 (29%) locations;

- High risk at 1,711 (9%) locations; and
- No peat was recorded at 4,401 locations (24%), hence no risk.

Figure 10.1.9 presents the interpreted risk of peat instability based on the multiplication of the risk coefficients discussed above in **Table 6-2** to **Table 6-4** and using the detailed mitigation in **Table 6-5**.

6.5 Wind Turbines

The peat stability risk rating for each proposed wind turbine is summarised in **Table 6-6.**

Table 6-6: Stability Risk Rating at Each Wind Turbine

Turbine No.	Peat Depth (m)	Substrate	Slope (^{0})	Stability Risk Rating	Acceptable Location
T1	0.5	Rock	6.9	Low	Yes
T2	0.5	Rock	6.4	Low	Yes
T3	0.4	Rock	14.0	Medium	Yes
T4	0.2	Rock	10.6	Low	Yes
T5	0.5	Rock	16.7	Medium	Yes
T6	0.4	Rock	6.6	Low	Yes
T7	0.4	Rock	10.3	Low	Yes
T8	0.1	Rock	10.1	Low	Yes
T9	0.1	Rock	6.4	Low	Yes
T10	0.4	Rock	8.5	Low	Yes
T11	0.6	Rock	3.7	Low	Yes
T12	0.4	Rock	13.9	Medium	Yes
T13	0.3	Rock	5.4	Low	Yes
T14	0.3	Rock	5.2	Low	Yes
T15	0.3	Rock	5.4	Low	Yes
T16	0.8	Granular	7.7	Low	Yes
T17	0.2	Rock	12.3	Medium	Yes
T18	0.5	Rock	11.3	Low	Yes
T19	0.2	Rock	6.5	Low	Yes
T20	0.6	Rock	6.3	Medium	Yes
T21	0.4	Rock	8.6	Low	Yes
T22	0.2	Rock	9.9	Low	Yes
T23	0.1	Rock	8.4	Low	Yes
T24	0.5	Rock	13.3	Medium	Yes
T25	0.9	Rock	2.7	Low	Yes

The table of results shows that the following potential stability risks exist at the proposed turbines:

- Low risk at 19 locations;
- Medium risk at 6 locations; and
- No high locations were identified.

6.6 Hardstandings

The peat stability risk rating for each proposed hardstanding is summarised in **Table 6-7.**

Table 6-7: Stability Risk Rating at Each Hardstanding

Hardstanding No.	Peat Depth (m)	Substrate	Slope (^{0})	Stability Risk Rating	Acceptable Location
T1	0.6	Rock	5.8	Medium	Yes
T2	0.7	Rock	7.8	Medium	Yes
T3	0.5	Rock	13.6	Medium	Yes
T4	0.8	Rock	6.8	Medium	Yes
T5	0.7	Rock	11.6	Medium	Yes
T6	0.3	Rock	10.7	Low	Yes
T7	0.4	Rock	10.2	Low	Yes
T8	0.5	Rock	11.4	Low	Yes
T9	0.6	Rock	7.1	Medium	Yes
T10	0.9	Rock	5.0	Medium	Yes
T11	1.0	Rock	3.6	Low	Yes
T12	0.4	Rock	17.7	Medium	Yes
T13	0.2	Rock	14.8	Medium	Yes
T14	1.0	Rock	7.7	Medium	Yes
T15	0.6	Rock	9.0	Medium	Yes
T16	0.5	Rock	9.6	Medium	Yes
T17	0.3	Rock	8.9	Low	Yes
T18	0.5	Rock	10.3	Low	Yes
T19	0.4	Rock	9.6	Low	Yes
T20	0.7	Rock	6.1	Medium	Yes
T21	0.5	Rock	7.1	Low	Yes
T22	0.4	Rock	11.6	Low	Yes
T23	0.5	Rock	12.6	Medium	Yes
T24	0.8	Rock	7.7	Medium	Yes
T25	0.4	Rock	8.5	Low	Yes

The table of results shows that the following potential stability risks exist at the proposed hardstandings:

- Low risk at 10 locations;
- Medium risk at 15 locations; and
- No high locations were identified.

6.7 Access Tracks

The results show that the majority of locations along the proposed access track show a negligible or low potential stability risk, with some areas of medium and high risk. **Figure 10.1.9**, Peat Slide Risk shows that the following potential stability risks exist across the Site at probing locations along the areas of new access track. Upgraded tracks along the existing B class road are not considered a risk due to the minor nature of the works. A detailed

geomorphological desk study has been undertaken and all the peat related features have been detailed in the aerial photography. From this plan the Site has been interrogated to identify significant high risk sites along the route which may impact upon the proposed development. This includes along the track and where it is identified as a potential risk upgradient and downgradient of the infrastructure. In many instances these areas are very limited, and the risk can be addressed. Where the risk is medium or high, the assessment has been taken to the next level and a hazard assessment completed in Section 6.15.

6.8 Remaining Infrastructure

The peat stability risk rating for each infrastructure element is summarised in **Table 6-8.**

Table 6-8: Stability Risk Rating at Infrastructure

Infrastructure Element	Peat Depth (m)	Substrate	Slope (°)	Stability Risk Rating	Acceptable Location
Substation	0.34	Granular	5.46	Negligible	Yes
Construction Compound North	0.88	Rock	3.74	Low	Yes
Construction Compound South	0.46	Granular	6.78	Negligible	Yes
Borrow Pit 1	0.31	Granular	11.21	Low	Yes
Borrow Pit 2	0.25	Rock	9.77	Low	Yes
Borrow Pit 3	0.28	Rock	10.68	Low	Yes
Borrow Pit 4	0.03	Granular	7.03	Negligible	Yes
Borrow Pit 5	0.50	Rock	11.43	Low	Yes

The table of results shows that the following potential stability risks exist at each infrastructure element:

- Negligible risk at 3 locations;
- Low risk at 5 locations; and
- No medium or high locations were identified.

6.9 Hazard Score Development

A further assessment of the medium and high risk locations has been undertaken. It should be noted that the impact assessment is primarily concerned with impacts that affect the environment, ecology, public or infrastructure associated with the development, both on-site and potentially off-site. These assessments do not consider the detailed ecological impact of construction induced peat instability; however, the majority of the sensitive on-site receptors are the watercourses and thus the inferred ecological and environmental issues are addressed. The proposed mitigation measures in Section 7.0 would limit the potential for any slope failures into water courses and drainage features hence limit such impacts.

The effect a slope failure may have on the construction site and infrastructure can be easily identified. However, the effect of an instability event on features impacted by an event not associated with the Development is harder to predict.

In order to address this effect, it is not considered appropriate to assess the effect at every potential receptor location close to a site; but rather to assess the effect a particular infrastructure feature (track, wind turbine, substation, etc.) would have on the structures or features surrounding it. By adopting such an approach, the assessment of infrastructure features where a risk ranking of ‘negligible’ or ‘low’ (assessed in the stability risk assessments described above) is discounted from further assessment.

6.10 Receptor Ranking

Now the infrastructure features with a 'medium' or higher risk rating for instability have been identified it is necessary to identify potential impact receptors. These are nearby structures or features that may be affected by peat movements caused during or following construction. Generally, only receptors immediately down gradient of the infrastructure feature could be affected by peat instability therefore the first phase of feature ranking requires topographic ridges and valleys to be identified across the Site and surrounding area. From this, receptors at risk from particular infrastructure features can be identified. However, should instability occur on a steep slope, there is the risk of the back scarp of the instability migrating up-slope, there-by affecting areas previously considered not to be at risk.

Following identification of receptors at risk, these are ranked according to their size and sensitivity. **Table 6-9** presents the coefficients placed on particular receptor types.

At the Site, only watercourses are deemed significant receptors potentially at risk from peat slides. Communities have been discounted due to distance from infrastructure, the impact therefore, should a slide occur is directly to water courses.

Table 6-9: Coefficients for Impact Receptor Ranking

Nature of Feature	Feature Coefficient
Non-critical infrastructure (minor/private roads, tracks)	1
Watercourses and critical infrastructure (pipelines, motorways, dwellings and business properties etc.)	3
Sub-Community (settlement 1-10 residents)	6
Community (settlement of >10 residents)	8

6.11 Receptor Proximity

The proximity of an impact receptor is also critical in assessing the likely level of disruption it may suffer following an instability event. Based on this, two further coefficients – distance from infrastructure feature and relative elevation differences between the infrastructure feature and impact receptor - are applied in deriving an impact ranking. **Table 6-10** and **Table 6-11** present the coefficients derived for distance and elevation of impact receptors.

Table 6-10: Coefficient for Impact Feature Distance

Distance from Coefficient Feature	Distance Coefficient
> 1km	1
100m – <1km	2
10 – <100m	3
0 – <10m	4

Table 6-11: Coefficient for Impact Feature Elevation

Relative Elevation of Feature	Elevation Coefficient
0 – <10m	1
10 – <50m	2
50 – <100m	3
> 100m	4

6.12 Impact Rating

The impact rating coefficient (score) is derived by multiplying the receptor ranking coefficient (score) by the distance coefficient (score) and the elevation coefficient (score) for each impact receptor associated with a particular infrastructure feature.

Based on distance to impact receptors, in this instance we have identified watercourses (which are the most sensitive receptor near the site). The other receptors have been discounted, either they are not present or distance to receptor mitigates risk. Watercourses are the principal receptor as they are at risk of not only direct impact from a peat slide but potentially the water course creates a pathway to impact other receptors indirectly, either ecological or potential water users downstream. Based on **Table 6-9** the watercourses would have an impact receptor coefficient (score) of 3 and then considering the distance to the receptor and the relative elevation differences on-site of receptors, a potential impact can be derived.

6.13 Hazard Ranking

The Scottish Government Guidance[1] recommends that the hazard ranking is assessed using the following formula:

1. **Hazard Ranking = Hazard x Exposure**

This philosophy can be applied to the assessment carried out so far in the following approach:

2. **Hazard Ranking = Risk Rating x Impact Rating**

In order to achieve a meaningful and manageable result from the hazard ranking, the results of the Risk Rating and Impact Rating have been normalised to a standard numerical scale, as detailed below in **Table 6-12**.

Table 6-12: Rating Normalisation

Risk Rating		Impact Rating	
Current Scale	**Normalised Scale**	**Current Scale**	**Normalised Scale**
Negligible <5	1	Very Low <10	1
Low 5 - <15	2	Low 11 - 20	2
Medium 15 - 30	3	High 21 - 30	3
High 31 - 50	4	Very High 31-50	4
Very High >51	5	Extremely High >51	5

The method of assessing probability of landslide, adverse consequence and hazard developed by SLR Consulting incorporates additional critical elements such as the substrate interface and coefficients for the receptor position, distance and elevation and as such is considered to be more rigorous than the assessment scheme proposed by the Scottish Government[1]. The ultimate Hazard Ranking scale does equate to the Scottish Government[1] scale, with hazard rankings divided over four zones.

A simple multiplication of these coefficients would result in potentially large and unwieldy risk and impact rating numbers. SLR has therefore opted to normalise these values to bring them in line with the values used in the Scottish Government Guidance[1], as illustrated in **Table 6-13**.

Table 6-13: Hazard Ranking

Hazard Ranking	Hazard Ranking Zone	Action
1-4	Insignificant	No mitigation action required although slide management and monitoring shall be employed. Slide management shall include the development of a Site specific construction plan for peat areas.
5 - 10	Significant	As for Insignificant condition plus further investigation to refine the assessment combined with detailed quantitative risk assessment to determine appropriate mitigation through relocation or re-design.
11 - 16	Substantial	Consideration of avoiding project development in these areas should be made unless hazard mitigation can be put in place without significant environmental effect.
17-25	Serious	Unacceptable level of hazard; development within the area should be avoided.

6.14 Results

The stability risk assessment has demonstrated that the majority of the Site lies within an area of negligible to low risk (62% of probe locations) with regards to stability based on **Figure 10.1.9**.

38% of probe location identified a medium or high risk of peat instability across the Site. Following review, the majority of these locations are not considered to have either a potential impact on the development infrastructure, due to locality, either well away from influencing infrastructure, in a down gradient position or have no impact on the local watercourses (receptors). Therefore 25 medium risk and 50 high risk sites have been identified and are discussed in the following section.

The stability risk assessment results presented in **Table 6-14** shows the calculated hazard ranking associated with every location where there is a stability risk of medium or above, at or close to infrastructure. The particular mitigation measures to reduce the risk of instability occurring are dependent upon location and the type of proposed structure. Proposed mitigation measures and actions already undertaken to reduce the risk of peat instability occurring are also identified in **Table 6-14**, together with the associated, revised hazard ranking. A more detailed discussion of the possible mitigation measures is presented in Section 7.0.

6.15 Hazard Rated Locations

As noted in **Figure 10.1.9** and, where the risk assessment has identified a negligible or low risk of peat instability, no specific mitigation measures are necessary. However, in order to ensure best practise is employed, there would be a need for careful monitoring and the construction management must include careful design of both the permanent and temporary works appropriate for peat soils; these are discussed further in Section 7.0.

The areas of the infrastructure that were rated as medium or high risk, or above, were subjected to a hazard assessment; a number of areas were discounted as they were located off the proposed access track and do not fall within influencing distance of any of the key proposed Site infrastructure. There is a significant number of medium or high risk sites located along tracks, this is predominantly a function of localised pockets of thick peat on steep slopes overlying bedrock. The model in fact increases the risk factor where bedrock is the underlying substrate rather than a glacial material which is predominantly granular. The risk factor therefore is very conservative and will be mitigated through good construction techniques including appropriate drainage and excavation to minimise risk.

The procedure adopted was to review **Figure 10.1.9** and identify those areas with a medium risk or greater, that were in close proximity or influencing distance of any of the proposed infrastructure or watercourses. Those risk areas where there is no development would not affect the natural stability of the peat.

The assessment carried out in **Table 6-14** was completed as described in the sections above. For example, Location 1 has a risk rating of 4 (derived from **Table 6-5**) with an impact rating of 2 (derived from the process described in Section 6.11 and normalised in **Table 6-12**). These ratings are multiplied (4x2) to give a hazard ranking of 8 (significant), as detailed in **Table 6-14.**

Although the potential hazards identified in **Table 6-14** can be mitigated to 'insignificant' it is believed that hazards should be subject to further post consent investigation and on-going monitoring during construction. Further details of mitigation during construction are described in Section 0.

Table 6-14: Stability Hazard Ranking Assessment

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
Location	Coordinates (E, N)	Risk Rating	Impact Rating	Hazard Ranking	Mitigation	Revised Hazard Ranking
1	131920, 914664	High	Low	Significant	Model impacted by very localised areas of deep peat (>1.5m) overlying bedrock at T1 turbine location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant
2	131975, 914692	Medium	Low	Significant	Model impacted by localised areas of thin peat (<1.5m) overlying bedrock at T1 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant
3	132368, 914576	Medium	Very Low	Insignificant	Model impacted by steep slope and localised areas of thin peat (<1.5m) overlying bedrock at T2 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
4	131065, 914314	High	Low	Significant	Model impacted by very steep slope and very localised pocket of thick peat (>4m) overlying bedrock at T3 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant
5	131041, 914172	High	Low	Significant	Model impacted by very steep slope and localised areas of thick peat (>2m) overlying bedrock at T3 turning head location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
6	131139, 914006	High	Low	Significant	Model impacted by steep slope and localised areas of thick peat (>2m) overlying bedrock along access track between T3 and T9. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant
7	131292, 913852	Medium	Very Low	Insignificant	Model impacted by moderate slope and localised areas of thin peat (<1.5m) overlying bedrock at T9 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
8	131600, 914326	High	Low	Significant	Model impacted by moderate slope and localised areas of thick peat (>3m) overlying bedrock at T4 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southwest. Micro-siting to the east would negate the excavation of thick peat and reduce risk.	Insignificant
9	131964, 914127	High	Low	Significant	Model impacted by very steep slope and localised areas of thick peat (>3m) overlying bedrock at T5 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
10	131947, 914053	High	Very Low	Insignificant	Model impacted by very steep slope and localised areas of thin peat (<1.5m) overlying bedrock at T5 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
11	132248, 913800	High	Low	Significant	Model impacted by steep slope and localised areas of thin peat (<1.5m) overlying bedrock at T8 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southwest.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
12	132454, 914275	High	Very Low	Insignificant	Model impacted by very steep slope and localised areas of thick peat (>2m) overlying bedrock north of substation location. Current design of floating roads in this section and good construction practices to reduce risk and mitigate peat landslide to the southwest.	Insignificant
13	132730, 914332	High	Low	Significant	Model impacted by very steep slope and localised areas of thin peat (<1.5m) overlying bedrock along access track to T6. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the west.	Insignificant
14	132948, 914072	High	Very Low	Insignificant	Model impacted by localised areas of thick peat (>2m) overlying bedrock along access track to T7. Excavation of localised peat deposits prior to construction or micro-siting track to north would reduce risk and mitigate peat landslide to the north.	Insignificant
15	133265, 913994	Medium	Low	Significant	Model impacted by steep slope and localised areas of thin peat (<1.5m) overlying bedrock at T7 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
16	131311, 913748	Medium	Low	Significant	Model impacted by localised areas of thin peat (<1.5m) overlying bedrock at T9 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
17	131405, 913561	High	Low	Significant	Model impacted by area of thick peat (>2m) overlying bedrock located to the northeast of junction south of T9. Excavation of localised peat deposits prior to construction or micro-siting track to west would reduce risk and mitigate peat landslide to the east.	Insignificant
18	131197, 913490	Medium	Low	Significant	Model impacted by localised areas of thick peat (>1.5m) overlying bedrock at T10 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southwest.	Insignificant
19	131108, 913431	Medium	Low	Significant	Model impacted by steep slope and localised area of thin peat (<1.5m) overlying bedrock at T10 turbine location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southwest.	Insignificant
20	131533, 913582	High	Low	Significant	Model impacted by very steep slope and localised areas of thick peat (>2m) overlying bedrock along access track to T10. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
21	131690, 913597	Medium	Low	Significant	Model impacted by localised areas of thick peat (> m) overlying bedrock along access track to T10. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the west.	Insignificant
22	131800, 913465	High	Very Low	Insignificant	Model impacted by localised areas of thick peat (>2m) overlying bedrock at T11 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the west.	Insignificant
23	131935, 913044	High	Low	Significant	Model impacted by very steep slope and thin peat (<1.5m) overlying bedrock along access track to T15. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
24	133376, 913192	High	Low	Significant	Model impacted by localised areas of thick peat (>1.5m) overlying bedrock at T15 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the south.	Insignificant
25	131847, 913183	High	Low	Significant	Model impacted by steep slope and thick peat (>2m) overlying bedrock along access track to T12. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the north.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
26	131341, 913216	Medium	Low	Significant	Model impacted by steep slope and thin peat (<1.5m) overlying bedrock north of access track heading west to T12. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant
27	131478, 913251	High	Low	Significant	Model impacted by steep slope and localised areas of thick peat (>2m) overlying bedrock at T14 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east and south.	Insignificant
28	130709, 913094	High	Very Low	Insignificant	Model impacted by very steep slope and localised areas of thick peat (>3m) overlying bedrock north of access track heading west to T12. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant
29	130803, 912923	Medium	Low	Significant	Model impacted by very steep slope and thin peat (<1.5m) overlying bedrock north of access track heading southwest to T12. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
30	130365, 913007	High	Very Low	Insignificant	Model impacted by steep slope and thin peat (<1.5m) overlying bedrock north of access track heading southwest to T12. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
31	130479, 912677	High	Low	Significant	Model impacted by steep slope and localised areas of thick peat (>2m) overlying bedrock at T12 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant
32	130810, 912816	High	Low	Significant	Model impacted by very steep slope and localised areas of thick peat (>3m) overlying bedrock at T12 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the south.	Insignificant
33	131378, 912931	Medium	High	Significant	Model impacted by thick peat (>1.5m) overlying bedrock to the west of T13 hardstanding. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant
34	130995, 913102	High	Low	Significant	Model impacted by very steep slope and thin peat (<1.5m) overlying bedrock at T13 hardstanding location. Excavation of peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
35	130469, 912997	High	Very Low	Insignificant	Model impacted by very steep slope and localised thin peat (<1.5m) overlying bedrock to the north of access track south of T12. Risk would be reduced by micro-siting track south and benching slope to mitigate risk of peat landslide.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
36	130351, 912606	High	High	Substantial	Model impacted by and localised area of thick peat (>3m) overlying bedrock to the north of access track south of T12. Risk would be reduced by micro-siting track south and benching slope to mitigate risk of peat landslide.	Insignificant
37	130624, 913009	High	Low	Significant	Model impacted by very steep slope and localised area of thick peat (>1.5m) overlying bedrock to the north of access track south of T12. Risk would be reduced by micro-siting track east and benching slope to mitigate risk of peat landslide.	Insignificant
38	130646, 912078	High	Low	Significant	Model impacted by very steep slope and localised areas of thick peat (<2.5m) overlying bedrock at T16 turbine location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the southeast.	Insignificant
39	132485, 912976	High	Very Low	Insignificant	Model impacted by very steep slope and localised areas of thick peat (<2m) overlying bedrock south of BP4 location. Current design of floating roads in this section and good construction practices to reduce risk and mitigate peat landslide to the south.	Insignificant
40	132964, 913276	Medium	Low	Significant	Model impacted by steep slope and areas of thin peat (<1.5m) overlying bedrock located to the east of turning head at T17. Risk would be reduced by micro-siting track west and benching slope to mitigate risk of peat landslide.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
42	132908, 912910	High	Low	Significant	Model impacted by steep slope and thin peat (<1.5m) overlying bedrock at T17 hardstanding location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
43	132915, 913171	High	Very Low	Insignificant	Model impacted by very steep slope and localised areas of thin peat (0.5m) overlying bedrock on access track leading to T18. Current design of floating roads in this section and good construction practices to reduce risk and mitigate peat landslide to the northwest.	Insignificant
44	133253, 913191	Medium	Low	Significant	Model impacted by thin peat (<1.5m) overlying bedrock at T18 turbine location. Excavation of localised peat deposits prior to construction would reduce risk and mitigate peat landslide to the east.	Insignificant
45	130173, 912273	Medium	Low	Significant	Model impacted by very steep slope and localised area of thick peat (<2m) overlying bedrock to the west of access track north of T21. Risk would be reduced by micro-siting track east and benching slope to mitigate risk of peat landslide.	Insignificant
46	130152, 912503	High	Low	Significant	Model impacted by steep slope and localised area of thick peat (>1.5m) overlying bedrock on access track north of T21. Risk would be reduced by micro-siting track and benching slope to mitigate risk of peat landslide.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
47	130465, 912204	Medium	Very Low	Insignificant	Model impacted by localised area of thin peat (<1.5m) overlying bedrock to the north of access track north of BP5. Risk would be reduced by micro-siting track south and benching slope to mitigate risk of peat landslide.	Insignificant
48	130811, 912165	Medium	Low	Significant	Model impacted by steep slope and localised area of thin peat (<1.5m) overlying bedrock on access track north of T20. Risk would be reduced by excavation of peat deposits and benching slope to mitigate risk of peat landslide.	Insignificant
49	130286, 912176	High	Low	Significant	Model impacted by very steep slope and localised areas of thin peat (<1.5m) overlying bedrock on the access track north of T20. Risk would be reduced by excavation of peat deposits and benching slope to mitigate risk of peat landslide.	Insignificant
50	130494, 911964	High	Low	Significant	Model impacted by steep slope and localised areas of thick peat (<2m) overlying bedrock on access track north of BP5. Risk would be reduced by excavation of peat deposits and benching slope to mitigate risk of peat landslide.	Insignificant
51	130246, 911903	High	High	Substantial	Model impacted by steep slope and localised area of thin peat (<1.5m) overlying bedrock to the south of access track north of T21. Risk would be reduced by micro-siting track south and benching slope to mitigate risk of peat landslide.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
52	130016, 911254	High	Low	Significant	Model impacted by steep slope and very localised thick peat (>3m) overlying bedrock at T22 hardstanding location. Excavation of peat deposits prior to construction would reduce risk and mitigate peat landslide to the south.	Insignificant
53	130121, 911619	Medium	Low	Significant	Model impacted by thin peat (<1.5m) overlying bedrock at temporary compound south location. Excavation of peat deposits prior to construction would reduce risk and mitigate peat landslide to the north.	Insignificant
54	130304, 911678	Medium	Low	Significant	Model impacted by localised areas of thick peat (>1.5m) overlying bedrock at T21 hardstanding location. Excavation of peat deposits prior to construction would reduce risk and mitigate peat landslide to the north.	Insignificant
55	130390, 911680	Medium	Low	Significant	Model impacted by steep slope and thick peat (>1.5m) overlying bedrock at the northwest corner of BP5. Excavation of peat deposits would reduce risk and mitigate peat landslide to the north.	Insignificant
56	130454, 911654	High	Low	Significant	Model impacted by very steep slope and thin peat (<1.5m) overlying bedrock within the footprint of BP5. Excavation of peat deposits would reduce risk and mitigate peat landslide to the north.	Insignificant

Hazard Area		Unmitigated Hazard			Mitigated Hazard	
57	130512, 911760	High	Low	Significant	Model impacted by very steep slope and localised areas of thin peat (<1.5m) overlying bedrock south of access track heading to T20. Risk would be reduced by excavation of peat deposits and benching slope to mitigate risk of peat landslide.	Insignificant
58	130613, 911837	Medium	Low	Significant	Model impacted by steep slope and localised area of thick peat (<2.5m) overlying bedrock on the western edge of T20 hardstanding. Excavation of peat deposits would reduce risk and mitigate peat landslide to the north.	Insignificant

7.0 Construction Issues and Mitigation Measures

It has been shown that excavation, drainage and general construction activities can have a destabilising influence on peat and that design should allow for the delicate and susceptible condition of the peat. There is no extensive evidence for past peat instability on-site, however appropriate good practice measures and mitigation should be employed to minimise the risk of adverse effects on peat and hydrological receptors.

The following sections highlight the construction issues that should be considered for each general area of construction. Many of the issues raised would be incorporated into the Site specific CEMP and construction method statement for the Site.

The following is a list of controls that should be considered for incorporation into the development of construction methodologies for the works in all areas of peat during detailed design stage:

- appropriately experienced and qualified engineering geologist/geotechnical engineer is appointed during the construction phase, to provide advice during the setting out, micro-siting and construction phases of the works;
- geotechnical Risk Register is developed and maintained by the appointed geotechnical engineer;
- a minimisation of “undercutting” of peat slopes, but where this cannot be avoided, a more detailed assessment of the area of concern by the geotechnical engineer would be required;
- careful micro-siting of wind turbine bases, crane hardstanding’s and access track alignments to minimise effects on the prevailing hydrology;
- although the risk of a peat slide following implementation of mitigation is considered to be low for the majority of the development, it is recommended that methodologies should be developed as a contingency to minimise the effects to watercourses in the unlikely event of peat instability; and
- use of floating track across areas of deep peat.

During the design phase, areas of thick peat present in flatter expanses of the Site have been avoided where possible to minimise disturbance and excavation of deep peat. Where deep peat cannot be avoided in the proposed track design, floated roads have been proposed to mitigate impacts to peat. For example, there are areas of access tracks in the centre of the Site near T4, T5, T8 and T11 that are proposed to be floating. In addition, sections of floating road have been proposed in the west of the Site near T18 and the south of the Site near T19 and T24.

Notwithstanding any of the above comments, detailed design and construction practices would need to consider the particular ground conditions and the specific works at each location throughout the construction period.

The following list of mitigation measures is provided in an attempt to minimise the risk of potentially inducing peat landslides during construction of the Development.

7.1 General

The following list of mitigation measures is provided in an attempt to minimise the risk of potentially inducing peat landslides during construction of the development.

- raise Health and Safety awareness of the peat environment at the proposed Development for construction staff by incorporating the issue into the Site Induction. Include peat slide risk assessment information (e.g. peat instability indicators, best practice and emergency procedures) in toolbox talks with relevant operatives e.g. plant drivers;

- introduce a 'Peat Hazard Emergency Plan' to provide instructions for Site staff in the event of a peat slide or discovery of peat instability indicators;
- for sections of track that require track side cuttings into peat, suitable support measures would need to be designed to maintain the stability of the adjacent peat terrain;
- refine/optimise the design through the pre-construction phase following completion of a detailed ground investigation; and
- develop methodologies to ensure that accelerated degradation and erosion of exposed peat deposits does not occur as the break-up of the peat top mat has significant implications for the morphology, and thus hydrology, of the peat (e.g. minimise off-track plant movements within areas of peat).

7.2 Drainage Measures

Drainage design for the Development is a critical mitigation measure in maintaining the hydrological conditions. In order to maintain hydrological conditions, the following requirements of the drainage measures should to be met;

- development of drainage systems that would not create areas of concentrated flow or cause over-, or under-, saturation of peat habitats;
- development of robust drainage systems that would require minimal maintenance;
- a robust design of drainage systems and associated measures (i.e. silt traps, etc.) to minimise sedimentation into natural watercourses. Method statements should be prepared in advance to mitigate against a slide occurring and should include, but not be limited to, the use of check dams and erosion protection to limit flows and prevent contamination of watercourses; and
- measures shall be put in place to ensure drainage systems are well maintained, to include the identification and demarcation of zones of sensitive drainage or hydrology in areas of construction, e.g. inclusion of maintenance regimes for drainage systems into a construction management plan or similar.

7.3 Construction Recommendations

A summary of recommendations for Site specific infrastructure is provided in the following sections.

The complexity of peat stability has been discussed in this report and by Lindsay and Bragg[2], amongst others. Following a review of published work and the observation and analysis undertaken for the development, there would be a negligible hazard from peat instability if the recommendations contained in this report are adopted.

Suitable guidance and documentation in the form of a construction method statement/CEMP would be established before work commences to ensure good construction practices. Due to the complex inter-reactions affecting peat stability it is proposed that the recommendations given below are used as a set of guidelines to generate a detailed design concept. The concept should include the range of potential risks discussed in this report and the design should be sufficiently flexible to allow for continual modification and up-dating as construction progresses.

7.4 Wind Turbine Locations and Crane Pads

It is proposed that construction of the wind turbine foundations will require excavation of peat and subsoil to create a suitable area for the foundation of the base.

It is the objective of this assessment to consider the potential risk from peat instability and to recommend solutions and mitigation measures to eliminate, or at least reduce the risk to a manageable level. Risk reduction can best be achieved by minimising the effect of any construction works and an appropriate CEMP/construction

method statement is an integral element in ensuring that all parties understand and acknowledge the potential consequences of a peat slide.

In general, the bearing stresses imposed by a wind turbine are relatively low and the main requirement of the base is to resist the overturning moments generated by the wind acting on the turbine. Gravity base foundations are designed to control bearing pressures to a level appropriate to the local ground conditions and provide stability against turbine loading.

The excavations for wind turbine bases and crane pads should be kept to a minimum where possible but it is likely that the required hard stratum would be typically several metres deep, beneath soft materials (peat), unless directly on rock. The very soft nature of peat means that unsupported cut or excavated slopes could be unstable unless shallow gradients are used. The overall width of such an excavation would be around 33m diameter at the original ground surface, depending on the thickness of the peaty soil/peat and glacial till and appropriate methods of stabilising the temporary slopes should be considered. Foundation excavation would produce large volumes of peat and this should be reused across the Site in an environmentally acceptable manner for restoration. Peat would not be used to back fill the excavation void within the footprint of the foundation as it would have a very low strength. Peat could be used as backfill outside the foundation footprint and also to dress verges to tracks and around wind turbine bases, in line with current Waste Management guidance[14]. Management of the water in the peat, by maintaining existing drainage during excavation is essential to avoid creating conditions likely to increase the risk of a peat slide.

7.5 Borrow Pits

The proposed borrow pits would be required to comply with appropriate construction and quarrying regulations. They have been deliberately sited to avoid excavating peat and no significant construction mitigation would be required. Should blasting of rock be required during excavation, it is not likely to increase the likelihood of a peat slide as the borrow pits have been proposed in locations with limited peat. For further details on proposed borrow pits, refer to **Technical Appendix 10.3: Borrow Pit Appraisal**.

7.6 Access Tracks

The general principles regarding the construction of the access tracks in peat that minimises the risk of instability and environmental effects are discussed below.

In order to maintain the current level or improve the stability of the peat mass on the slopes around the access track, it is necessary to ensure that the construction methods do not seriously disrupt the established drainage and that no areas are surcharged, either by water discharge or spoil.

Wherever possible, the following principles should be adopted:

- maintenance of existing drainage is critical therefore all existing drainage tracks must be maintained and where necessary, channelled below the proposed track construction. Upslope side drainage ditches to the track would be required on side-long ground; the ditches should be constructed with small dams and cross drains where necessary so that:
- water can pass below the track at regular intervals;
- scour and erosion is avoided in the side ditches due the limited volume and velocity, concentrated discharges to the peat on the down slope side of the track are avoided;
- the camber of the track should encourage surface water to drain to the up-slope side drainage ditch;

[14] Scottish Renewables and SEPA (2012). Developments on Peatland: Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste.

- track gradients to be maintained at the recommended gradients from the wind turbine supplier, typically shallower than 1 v : 8 h to facilitate access by the large specialist vehicles for both construction and transport of the wind turbine components. The maximum acceptable gradients are usually defined by the appointed wind turbine manufacturer.
- identify and mark all existing drainage features within the access track corridors; these drainage features should be maintained (not enhanced) during the construction and operational phases of the development;
- install cross drains at regular intervals to maintain interstitial groundwater flow through the peat mass below the tracks where track settlement could reduce the natural permeability;
- install additional drainage in areas up-slope to any track to prevent ponding and possible instability;
- install small dams at regular intervals along the track side drains to prevent significant water velocities in the side drains causing deep erosion in the peat;
- where track construction is required over peat areas in excess of 1m deep, this may be undertaken with a floating track construction, where the integrity of the peat allows; and
- cut and fill should be avoided in peat greater than 1m deep if possible; if not, the following requirements on side long ground (across contours) should be adopted:
    - excavate to a sound stratum;
    - the majority of construction surface's to be essentially horizontal with a slight fall to aid drainage;
    - where the depth of cut is deemed unstable, employ a stepped or benched surface with the intention of minimising the exposed surface of the up-slope cut face;
    - protect all exposed peat surfaces from erosion and desiccation, by ensuring the integrity and moisture content of the peat is maintained; and
    - the top of cut slopes should be provided with a small bund to retain the peat to prevent desiccation and maintain the local stability of the peat.

7.7 Cable Routes

The general principles regarding the construction of the cable trenches in peat that minimises the risk of instability and environmental effects are discussed below.

In order to maintain the current level or improve the stability of the peat mass on the slopes around the cable route, it is necessary to ensure that the construction methods do not seriously disrupt the established drainage and that no areas are surcharged, either by water discharge or spoil.

The construction of the cable route would minimise disturbance to drainage by taking cable route alongside existing access track and around the wind turbines adjacent to new tracks. Cable trenches would be reinstated as soon as possible to minimise the time they are left open and to avoid trenches acting as conduits for surface water, causing erosion and potential silt run off.

Mitigation may be required within the trench to maintain local hydrological conditions and hydraulic connection in sensitive habitats. This may include clay plugs/ peat bunds to prevent the trenches from becoming a preferential flow path for water flows.

7.8 Watercourses Crossing

The access tracks will cross existing watercourses at a number of locations and care would be required to ensure conformity in the settlement characteristics between the crossing structure and the approaches to avoid undue settlement. The preferred option for the stream crossings will be with the use of culverts and bridges. The larger

watercourse crossings will not be influenced by peat. Watercourse crossing designs will be subject to the approval of SEPA.

7.9 Substation

The position of the substation compound is located on areas of thin peat on relatively flat ground and will require minimal construction management.

7.10 Construction Compound

The temporary construction compounds are located on areas of thin peat on relatively flat ground and will require minimal construction management.

8.0 Conclusion

The report has highlighted the complicated inter-relationship between all the aspects that have an effect on the stability of peat. Consequently, the discussion has also addressed areas of construction and drainage in order to avoid a stability problem rather than attempt to put it right after the event. The Site has been assessed for potential hazards associated with peat instability; the assessment has been based on:

- a walk-over survey by an experienced geologist;
- a thorough inspection of the digital terrain map;
- review of historical and geological maps and publications and aerial photography; and
- a detailed geotechnical probing exercise at 18,241 locations in areas of identified peaty soil/peat to determine the thickness thereof.

The overall conclusion regarding peat stability is that there are significant areas of medium and high risk of peat instability across the Site although most have these have been avoided during the design process. For the medium and high risk areas, a hazard impact assessment was completed which concluded that, subject to micro-siting and the employment of appropriate mitigation measures, all of the areas can be considered as an insignificant risk.

Additional mitigation measures have been identified in areas where hazards are already considered insignificant to further reduce the risk of potential hazards occurring.

The entire Site can be considered to be extensively covered in peat the more extensive areas of deep peat have been avoided through the iterative design process.

This Technical Appendix should be considered as the first stage in the development of a fundamental understanding of the various inter-relationships that govern and control the peat lands at the proposed development.

The commissioned assessment has purposefully kept the extent of physical intrusion into the sensitive peat areas to an absolute minimum. The results are considered appropriate for the planning application.

More detailed ground investigations will be required to facilitate the geotechnical design of the various foundations and access track, particularly the vertical and horizontal alignment and the design of the river/stream crossings. These will be incorporated into the Construction Method Statement which will be submitted to the Planning Authority for approval as part of the condition compliance prior to any site works commencing.

It is not the purpose of this report to provide a detailed scope for the investigation; however, it is believed that the strength and stiffness parameters are needed for turbine design and regular probes along access tracks to determine bearing capacity for either excavated or floated track design.

Peat Core Log

Hole No. **PC01**

Sheet 1 of 1

Project: Uisenis Wind Farm EIA	Client: Eurowind Energy Ltd		Date: 03/11/2023
Project No: 405.V64341.00001	Logger: ET		Coordinates: E: 130805.00 N: 911759.00
Location: Isle of Lewis	Hole Type: PC	Method:	Vertical Scale: 1:26

Water	Depth (m)	Sample Type	Depth	Recovery (%)	Depth (m) / Discontinuity Detail	Level (mAOD)	Legend	Stratum Description
	0.00 - 0.50	C	0.00 - 0.50	Recovery = 100%	0.50			Dark brown amorphous PEAT. Moderate decomposition, plant structure is recongisable but vague. Considerable amount of amorphous material. When squeezed, muddy water and some peat extruded. Residue strongly pasty (H5).
	0.50 - 1.00	C	0.50 - 1.00	Recovery = 100%	1.50			Dark brown amorphous PEAT. Moderately strong decomposition, indistinct plant structure. Considerable amount of amorphous material. When squeezed, approximately 1/3 of peat squeezed out and some dark brown muddy water. Residue strongly pasty (H6).
	1.00 - 1.50	C	1.00 - 1.50	Recovery = 100%	2.00			Dark brown amorphous PEAT. Poor recovery due to complete degradation and high water content. Plant structure non discernable. Very high content of amorphous material and when squeezed, all peat passes between fingers (H10).
	1.50 - 2.00	C	1.50 - 2.00	Recovery = 100%	2.70			Dark brown amorphous PEAT. Decomposition nearly complete, plant structure almost unrecognisable. Very high content of amorphous material. Nearly all peat squeezed out as uniform paste (H9).
	2.00 - 2.50	C	2.00 - 2.50	Recovery = 100%				
	2.50 - 2.70	C	2.50 - 2.70	Recovery = 100%				Peat Core Complete at 2.70m

Remarks:

Peat core recovered using peat sampler.

TECHNICAL APPENDIX 10.2: PEAT MANAGEMENT PLAN

Uisenis Wind Farm

Prepared for: **Uisenis Power Limited**

SLR Ref: 405.V64341.00001
Version No: 1
August 2023

BASIS OF REPORT

This document has been prepared by SLR with reasonable skill, care and diligence, and taking account of the manpower, timescales and resources devoted to it by agreement with Uisenis Power Limited (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

Annex A: Excavated Materials Calculations

1.0 Introduction

This Stage 1 Peat Management Plan (PMP) has been undertaken by SLR Consulting Ltd (SLR).

The proposed Uisenis Wind Farm (proposed development) is located approximately 20km south west of Stornoway, on land within the Eisgen (Eishken) Estate on the Isle of Lewis (the Site) as shown on **Figure 10.2.1**. The Site is currently accessed via an unnamed road (Eishken Road) off the A859 between Balallan and Kintarvie. The road spans approximately 12.07km from the A859 to the Eishken Estate Lodge.

The proposed development would comprise 25 wind turbines with associated infrastructure:

- associated turbine formations and transformers;
- hardstanding areas for erecting cranes at each turbine location;
- upgrading of existing road and tracks;
- series of on-site access tracks connecting each turbine;
- underground cables linking the turbines to the grid connection;
- on-site substation compound;
- temporary construction compound(s);
- turning heads;
- meteorological masts; and
- borrow pit(s).

The Site layout is detailed on **Figure 10.2.2**. For a full description of the proposed development, please refer to Environmental Impact Assessment Report (EIA Report) **Chapter 3: Description of Development**.

1.1 Scope of Assessment

A comprehensive programme of soils and peat probing has been completed at the Site, detailed within **Technical Appendix 10.1: Peat Landslide and Hazard Risk Assessment (PLHRA)**. This document uses this information and provides indicative volumes for peat extraction and outlines recommendations for the handling, re-use and storage of peat during construction and operation of the Site.

Areas of the Site where soils are less than 0.5m thick are considered to be too thin to be classified as peat and are therefore classified as soils.

The purpose of this report is to ensure that there has been a systematic consideration of peat management and a quantitative assessment throughout the design process.

1.2 Methodology

1.2.1 Requirements of National Planning Policy 4

The intent of Policy 5 (Soils) of National Planning Policy 4 (NPF4)[1] is "*to protect carbon rich soils, restore peatlands and minimise the disturbance of soils from development*".

1 Scottish Government (2023). https://www.gov.scot/binaries/content/documents/govscot/publications/advice-and-guidance/2022/11/national-planning-framework-4-revised-draft/documents/national-planning-framework-4-revised-draft/national-planning-framework-4-revised-draft/govscot%3Adocument/national-planning-framework-4-revised-draft.pdf

The Policy states [5(a)] that development proposals should only be supported if they are designed and constructed:

- in accordance with the mitigation hierarchy by first avoiding and then minimising the amount of disturbance to soils on undeveloped land; and
- in a manner that protects soils from damage including from compaction and erosion, and that minimises soils sealing.

Further [5(c)] confirms that development proposals on peatland, carbon rich soils, and priority peatland will only be supported if:

- essential infrastructure and there is a specific locational need and no other suitable site;
- the generation of energy from renewable sources that optimises the contribution of the area to greenhouse gas emissions reductions targets;
- small-scale development directly linked to a rural business, farm or croft;
- supporting a fragile community in a rural or island area; or
- restoration of peatland habitats.

And [5(d)] confirms that where development on peatland, carbon-rich soils or priority peatland habitat is proposed, a detailed site specific assessment will be required to identify:

- the baseline depth, habitat condition quality and stability of carbon rich soils;
- the likely effects of the development on peatland, including on soil disturbance; and
- the likely net effects of the development on climate emissions and loss of carbon.

Policy 5 also confirms that the site specific (above) assessment [5(d)] "*should inform careful project design and ensure, in accordance with relevant guidance and the mitigation hierarchy, that adverse impacts are first avoided and then minimised through best practice. A peat management plan will be required to demonstrate that this approach has been followed, alongside other appropriate plans required for restoring and/ or enhancing the site into a functioning peatland system capable of achieving carbon sequestration*".

This Stage 1 PMP considers the protection and safeguarding of peat and seeks to fulfil the requirements of Policy 5(d).

1.2.2 Mitigation Hierarchy

SEPA[2,3] has published guidance regarding the mitigation hierarchy which is summarised below:

- Prevention – avoiding generating excess peat during construction (e.g., by avoiding peat areas or by using construction methods that do not require excavation such as floating tracks);
- Re-use – use of peat produced on site in restoration or landscaping, provided that its use is fully justified and suitable;
- Recycling / Recovery / Treatment – modify peat produced on site for use as fuel, or as a compost / soil conditioner, or dewater peat to improve its mechanical properties in support to re-use; and

[2] Scottish Environment Protection Agency. 2010. Regulatory Position Statement – Developments on Peat.
[3] Scottish Renewables, Scottish Environment Protection Agency. 2012. Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste.

- Storage – storage of peat up to a depth of 2m is not classified as a waste and does not require authorisation from SEPA, however care must be taken to ensure that it does not cause environmental pollution.

1.2.3 Relevant Legislation and Guidance

Legislation relevant to the management of peat includes the following:

- The UK Climate Change Act 2008 (c 27);
- Environmental Protection Act 1990 (as amended);
- Landfill (Scotland) Regulations 2003 (as amended); and
- The Waste Management Licensing (Scotland) Regulations 2011.
- National Planning Framework for Scotland 4 (NPF4) (Scottish Government, February 2023);

Relevant guidance includes:

- SEPA Regulatory Position Statement - Developments on Peat (Scottish Environment Protection Agency, 2010);
- Good Practice during Windfarm Construction, 4th Edition (Scottish Renewables, Scottish Natural Heritage (now NatureScot), Scottish Environment Protection Agency, Forestry Commission Scotland, Historic Environment Scotland, Marine Scotland Science and AEECoW, 2019);
- Peat Landslide Hazard and Risk Assessments: Best Practice Guide for Proposed Electricity Generation Developments (Scottish Government, January 2017);
- SNH Carbon and Peatland Map 2016;
- Floating Roads on Peat - Report into Good Practice in Design, Construction and Use of Floating Roads on Peat with reference to Wind Farm Developments in Scotland (Forestry Commission Scotland & Scottish Natural Heritage, 2010);
- Managing Geotechnical Risk: Improving Productivity in UK Building and Construction (Institution of Civil Engineers, 2001);
- Ground Engineering Spoil: Good Management Practice CIRIA Report 179 (CIRIA, 1997);
- Scottish Roads Network Landslides Study Summary Report (Scottish Executive, 2005); and
- Guidelines for the Risk Management of Peat Slips on the Construction of Low Volume/Low-Cost Roads on Peat (Forestry Commission, 2006).

1.2.4 Definition of Peat

Peat is defined as a material consisting of the partially decomposed remains of plant material and organic matter preserved over a period in a waterlogged environment resulting in anaerobic conditions, and is of depths > 0.5m.

Peat can be classed as two principal types, the acrotelm layer, and the catotelm layer as shown on **Plate 1-1**.

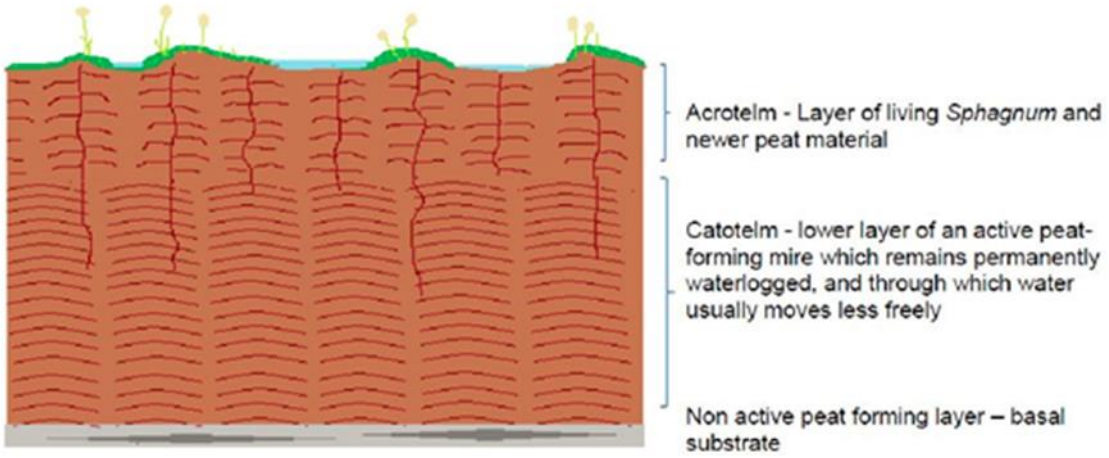

Plate 1-1 Drawing of two layered Structure of Active Bog Peatlands above Non-Active Peat

The acrotelm layer is found in the upper layer of peat where conditions are relatively dry and comprises living vegetation and partially decomposed plant material. Hydraulic conductivity in this layer tends to be higher in relation to distance from the water table. The thickness of the acrotelm layer varies depending on topography such as steepness of slope, peat hags, and hummocks. In particular, the acrotelm layer can be affected during periods of drought or as a consequence of drainage. Fibrous in texture, the acrotelm layer has some tensile strength and is generally considered to be stable for storage and re-use.

The catotelm layer is found under the acrotelm layer and comprises decayed plant material and organisms and is denser and with a very low hydraulic conductivity. The catotelm layer sits below the water table resulting in permanent anaerobic conditions. The catotelm layer is amorphous and has very low tensile strength making it less suitable for storage and re-use.

2.0 Site Work

2.1 Peat Depth Survey

Peat depth surveys have been undertaken across a number of phases by SLR and other parties. Existing peat probe data was carried out in support of the 2004 Muaitheabhal Wind Farm application, the 2010 Muaitheabhal Wind Farm Eastern Extension application, and the 2013 Muaitheabhal Wind Farm Southern Extension application (all now consented). This Peat Landslide Hazard Risk Assessment uses the peat depth data collected by SLR and also the peat depth data collected in support of the Muaitheabhal Wind Farm applications. The SLR surveys were carried out followed best practice guidance for developments on peatland[4,5].

Phase 1 peat probing resulted in probing on a 100m grid to allow for initial assessment of the Site which was used in preliminary Site layout designs. Phase 2 probing included detailed probing across the proposed infrastructure layout, focussing on access tracks, turbine locations and other Site infrastructure.

Peat is generally defined as an organic soil in excess of 0.5m, if the soil is less than 0.5m, then it is considered peaty soil. The peat was found to vary across the Site in terms of thickness and coverage.

Thin peat was classed as being 0.5m to 1.5m thick, with deposits in excess of this being classed as thick peat. The thickness ranges used were intended to reflect the probability of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded less than 0.5m thick, this has been considered to be an organic/peaty soil rather than peat.

The thickness of the peat was assessed using a graduated peat probe, approximately 6mm diameter and capable of probing depths of up to 10m. This was pushed vertically into the peat, to refusal, and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as ±2m, which was considered sufficiently accurate for this survey. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the 'feel' of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- solid and abrupt refusal – rock;
- solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- rapid and firm refusal – clay; or
- gradual refusal – dense peat or soft clay.

Where surveys were undertaken by SLR, an assessment of the substrate was made and recorded at each probe hole. For use within this assessment, engineering judgement has been used to assess the substrate at probes undertaken by other parties.

The relative stiffness of the peat was also assessed from the resistance to penetration of the probe and to the effort required to extract the probes. In all instances refusal was met on obstructions allowing identification of subsurface geology.

[4] Scottish Renewables & SEPA (2012) 'Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste'.
[5] Scottish Natural Heritage (SNH), SEPA, Scottish Government & James Hutton Institute. (2014)' Peat Survey Guidance; Developments on Peatland: Site Surveys'.

2.2 Peat Depth Results

The results from all probing exercises listed above are detailed in the following sections and the peat depths identified onsite are shown on **Figure 10.2.3** to **Figure 10.2.5**.

The peat was found to vary across the Site in terms of thickness and coverage. It is evident that the peat is generally limited to flat expanses that mimic the topographic flat lying areas. There were localised areas of peat on-site, defined by topography and undulating bedrock. Peat coverage was extensive throughout the centre of the Site and in localised areas in the north, east and south of the Site. Deeper peat was generally encountered in flatter, low gradient areas of the Site.

A total of 18,241 probe holes were undertaken across all survey phases, with the results summarised in **Table 2-1**.

The peat geomorphology and Site observations are provided within **Technical Appendix 10.1: Peat Landslide and Hazard Risk Assessment (PLHRA)** with the main relevant findings summarised below.

Table 2-1: Peat Probing Data

Peat Thickness (m)	No. of Probes	Percentage (of total probes undertaken on-site)
0 (no peat)	4401	24.1
0.01 – 0.49 (peaty soil)	6164	33.8
0.50 – 0.99	4323	23.7
1.00 – 1.49	1604	8.8
1.50 – 1.99	817	4.5
2.00 – 2.49	388	2.1
2.50 – 2.99	266	1.5
3.00 – 3.49	148	0.8
3.50 – 3.99	58	0.3
> 4.0	72	0.4

2.3 Peat Condition

Peat is described using the von Postclassification. Peat samples were collected by SLR in November 2022, using a peat auger and used to inform interpretations of the peat condition and underlying substrate.

Based on Site interpretations from probing and peat core samples, the peat within the Site boundary is predominantly amorphous and heavily degraded. There are some localised deposits of shallow peat that generally comprise fibrous to pseudo-fibrous layers, whilst areas of thicker peat are predominantly pseudo-fibrous to amorphous layers.

Based on field descriptions at augering points, most of the shallow peat would be classified as H5/H6 in the von Post classification, showing moderate decomposition with considerable amorphous material. Thick peat, in excess of 1.5m is more decomposed and generally between H7 and H10. The peat augering logs and photographs are provided within **Technical Appendix 10.1: Peat Landslide and Hazard Risk Assessment (PLHRA)**.

2.4 Substrate

Where possible, during the SLR peat probing, an assessment of the substrate was made, as described previously. From the evidence of the probing and sampling where available, the substrate falls into one of two principal categories:

- granular (sand and/or gravel/weathered rock), of glacial origin and occasionally interbedded with silty sands;
- rock, no rock samples were recovered from the probe locations although where exposed, the rock is observed to comprise metamorphic rock of the Lewisian Complex;
- the bedding dip and discontinuity spacing could not be determined at this stage but evidence from outcrops confirms the metamorphic rocks and should be subject to further investigation for the design of the turbine foundations; and
- limited cohesive horizons were interpreted by the probing, however evidence from the site walkovers did not encounter cohesive soils on site. It is likely that any cohesive material is weathered silty material at the top of the weathered glacial material.

2.5 Peat Depth at Infrastructure

The peat thickness and substrate at each proposed turbine and hardstanding location is summarised in **Table 2-2.**

Table 2-2: Ground Conditions at Each Wind Turbine and Hardstanding Locations

3.0 Potential Impacts on Peat from Construction Activities

3.1 Wind Turbines

Wind turbine foundations in peatlands would normally require full and permanent excavation of peat to competent strata, with temporary excavation of peat from a wider diameter to enable safe access to the base of the excavation.

The resulting peat generated could be considered as a permanent loss, unless satisfactory re-use could be achieved within the development Site. The peat would normally be used to reinstate track shoulders, around crane hardstandings and turbine bases.

3.2 Crane Hardstanding

In order to assemble the wind turbine and enable servicing during operation, crane pads are constructed adjacent to each wind turbine. The proposed crane hardstandings include areas that do not require intrusive groundworks, areas that do but are temporary, and areas that do and are permanent. The locations of the proposed turbines and the orientation of their crane pads has been designed in order to minimise impacts on deep peat and watercourses where possible. **Figures 10.2.5a-y** detail the layout of the proposed crane hardstandings. These must be sufficient to take the weight of both the crane and turbine components, and therefore excavation to underlying competent strata is required. Without adequate drainage controls, permanent excavation may disrupt natural hydrological pathways.

Crane pads must remain in place for the life of the proposed development to enable routine inspection and maintenance. Peat generated from these excavations would be considered a permanent loss, unless satisfactory re-use could be achieved within the development site.

3.3 Temporary Construction Compounds

Temporary construction compounds are provided during the construction phase to enable storage of construction materials, turbine components and fuel, concrete batching plant, siting of welfare facilities and Site offices.

Due to their temporary nature, peat excavated for compounds would normally be stored and reinstated, and therefore re-use is required.

3.4 Substation Compound

The substation compound location will likely require full and permanent excavation of peat to competent strata.

The resulting peat generated could be considered as a permanent loss, unless satisfactory re-use could be achieved within the development Site. The peat would normally be used to reinstate track shoulders or around the substation compound.

3.5 Borrow Pits

Where access track and hardstanding construction materials are required, it is intended to source the material from borrow pits onsite.

Peat overlying glacial till, weathered rock and bedrock is normally excavated and temporarily stored for the duration of construction, and then re-used for borrow pit restoration and landscaping post construction, and therefore re-use is required.

Borrow pits have been located to ensure that peat is shallow and therefore minimal peat would need to be excavated at each locations.

For further information on proposed borrow pits, refer to the **Technical Appendix 10.3: Borrow Pit Appraisal** (BPA).

3.6 Access Tracks

Access tracks are required to enable passage of construction and servicing traffic around the site. Over peatlands, the choice of access track design normally reflects the peat depths along the route, with shallow peat/organic soils <1.5m deep excavated to competent strata (cut and fill tracks), and deeper peats overlain by floating tracks (with no excavation) when slope gradients (<14%) are deemed suitable.

Access tracks are permanent infrastructure, peat excavated for cut and fill would be considered a permanent loss, unless the peat can be re-used elsewhere on Site.

No excavations are undertaken for floating tracks, and therefore there is no associated peat excavation.

In excavated tracks, the surface vegetation (i.e. habitat) would be lost unless stored and reinstated elsewhere, however the intention would be to re-use excavated turves and peat on verges and track shoulders (including along the verges of floated track sections) and hardstandings for landscaping and restoration purposes.

Both types of access track have the potential to disrupt natural hydrological drainage pathways, appropriate drainage would be designed to mitigate this. For further information, see **Technical Appendix 3.1: Outline CEMP**.

3.7 Cable Trenching

Electrical cabling is typically buried or ducted adjacent to the access track network where practicable (cable trenching), either into existing peat (requires excavation, laying and backfilling) or wherever possible ducts are laid within reinstated material at the sides of floated tracks (no excavation of in-situ peat required). Where excavation is required, peat generated from cable trenching is normally replaced at its point of origin, and therefore is not considered a volume loss and re-use is a certainty.

4.0 Proposed Mitigation During Construction

There are a number of ways in which detailed design and construction activities can be specified to minimise impacts on peatlands. The following section outlines briefly the likely mitigation required to minimise impact, based on the re-use of peat specific to key elements of the Site.

4.1 Wind Turbine Foundations

Wind turbine foundations represent permanent excavation, and the primary mitigation measure is to locate the wind turbines to avoid the areas of deepest peat, thereby reducing excavated volumes. 21 of the proposed turbines are located on peaty soil (< 0.5m) and four located on thin peat (0.5m - <1.5m). The average peat depth is 0.4m, ranging from 0.05m to 0.9m.

4.2 Hardstandings and Compounds

In relation to crane hardstanding, guidance is to avoid their full reinstatement post-construction, given the likelihood of re-use for maintenance activities associated with the wind turbines.

In relation to temporary compounds, the following good practice guidance applies:

- peat stripped from temporary compounds and hardstanding areas will not be stored higher than 1m and could require to be seeded in the short term to prevent drying out, if stored for long residence times;
- stripped turves are used for final restoration, however where turves are insufficient or vegetation regeneration requires reseeding, temporary fencing may be considered around compound areas undergoing restoration in order to prevent grazing; and
- the choice of seed mix for reseeding should be appropriate to the ecological and hydrological conditions of the restored compound location and surrounding habitats and should be advised by the Ecological Clerk of Works (ECoW).

4.3 Borrow Pits

Peat may be re-used within Borrow Pits for the purpose of their restoration provided the method of re-use is consistent with the environmental reinstatement objectives of the Site and presents no residual risks from pollution of the environment or harm to human health. Key issues for Borrow Pit restoration are:

- prevention of desiccation and carbon losses from peat used in the restoration;
- development of complete vegetation cover through emplacement of peat turves or seeding with an appropriate species; and
- fencing where required, to exclude grazing stock and to encourage vegetation establishment.

4.4 Access Tracks

In comparison to infrastructure specific to wind turbines, there is considerably more guidance[6,7] available to support access track design in peatlands. Guidance is generally focused on floating tracks and excavated tracks and is summarised below.

[6] Scottish Renewables, Scottish Natural Heritage, Scottish Environmental Protection Agency, Forestry Commission Scotland, Historic Environment Scotland, Marine Scotland, AEECoW (2019)., Good Practice During Wind Farm Construction. 4th Edition.
[7] Scottish Natural Heritage, Forestry Commission (August 2010)., Floating Roads on Peat

4.4.1 Floating Access Tracks

For the proposed development it is envisaged that floating tracks could be used in certain areas of peat >0.5m, to remove the requirement for peat excavation and limit disruption of hydrological pathways. The success of construction requires careful planning to take account of the unique characteristics of peat soils. Specific guidance[7] is available on design, the duration and timing of construction, the sequence of construction and the re-use of peat on the shoulders of the floating access track.

Design of Floating Access Tracks

The following issues should be considered during detailed design of floating access tracks:

- adopting conservative values for peat geotechnical properties during detailed design;
- applying a maximum depth rule whereby an individual layer of geogrid and aggregate should not normally exceed 450mm without another layer of geogrid being added;
- on gently sloping ground (below 5%) and where the access track runs transverse to the prevailing slope, accommodating natural hydrological pathways such as flushes and peat pipes through installation of a permanent conduit within or underneath the track and allowing for as much diffuse discharge (while minimising disturbance to existing peatland) on the downslope as possible;
- ensuring transitions between floating tracks and excavated tracks (or other forms of track not subject to long term settlement) are staged in order to minimise likelihood of track failure at the boundary between construction types;
- scheduling access track construction to accommodate for, and reduce peat settlement characteristics; and
- re-use of existing roads (with upgrading if required), where possible.

Duration and Timing of Construction of Floating Access Tracks

The critical factor in successful construction of floating access tracks is the timescale of construction, and the following good practice guidance is provided:

- the settlement characteristics of peat; should be accommodated by appropriate scheduling of access track construction, as follows:
    - prior to construction works, the setting out the centreline of the proposed access track to identify any ground instability concerns or particularly wet zones;
    - identifying ‘stop’ rules, i.e. weather dependent criteria for cessation of access track construction based on local meteorological data; and
    - maximising the interval between material deliveries over newly constructed access tracks that are still observed to be within the primary consolidation phase.

Sequence of Construction

The sequence of construction is normally stipulated in guidance provided by the supplier of the geotextile or geogrid layer, and suppliers are often involved in the detailed access track design. Good practice in relation to the sequence of access track construction is as follows:

- retaining rather than stripping the vegetation layer (i.e. the acrotelm, providing tensile strength), and laying the first geotextile/geogrid directly on the peat surface;
- adding the first rock layer;
- adding the second geotextile/geogrid, and add overlying graded rock fill as a running surface;

- heavy plant and Heavy Goods Vehicles (HGV) using the access tracks during the construction period should be trafficked slowly in the centre of the track to minimise dynamic loading from cornering, breaking and accelerating;
- ensuring wheel loads should remain at least 0.5m from the edge of the geogrid, markers should be laid out, monitored and maintained on the access track surface to clearly emphasise these boundaries; and
- ongoing 'toolbox' talks and subsequent feedback to construction and maintenance workers and drivers to emphasise the importance of the implementing the above measures.

Use of Peat as Trackside Shoulders

A key opportunity to re-use peat is to employ it in landscaping of constructed access tracks. Wedge-shaped reinstatement at the margins of a floating access track (which is elevated above the peat surface) is termed shoulders, and good practice guidance is as follows:

- re-using peat excavated from elsewhere on site as shoulders adjacent to the floating track;
- peat shoulders should taper from just below the track sides (thereby preventing over high shoulders from causing ponding on the track surface) to join the surrounding peat surface, keeping as natural a profile as possible to tie in with existing slope profiles;
- limiting the width of peat shoulders to avoid unnecessary smothering of intact vegetation adjacent to the floating track;
- peat must not be laid too thinly (minimum 0.5m) to avoid drying out;
- peat must not be compressed during reinstatement to prevent cracking; and
- where possible these should be capped with turves or seeded as quickly as possible to prevent run off erosion and should not be left bare for excessive periods.

4.4.2 Excavated Access Tracks

Excavated tracks require complete excavation of soil/peat to a competent substrate. Excavated tracks will generally be undertaken where peat depths are less than 1m. This peat/soil would require storage ahead of re-use elsewhere on Site. Good practice guidance relates mainly to drainage in association with excavated tracks:

- trackside ditches should capture surface water (within the acrotelm) before it reaches the road;
- interceptor drains should be shallow and flat bottomed (and preferably entirely within the acrotelm to limit drawdown of the water table);
- any stripped peat turves should be placed back in the invert and sides of the ditch to assist regeneration and prevent erosion to the peat and wash out that could occur; and
- culverts and cross drains should be installed under excavated tracks to maintain subsurface drainage pathways (such as natural soil pipes or flushes). Discharge from constructed drainage should allow for as much diffuse dispersion of clean (silt free) water as possible while minimising disturbance to existing peatland as far as possible. Silt mitigation measures will be incorporated into all constructed drainage as per the requirements of the CEMP.

Although excavation is normally undertaken in peat of minor thickness (< 1.5m), there is a possibility of minor slippage from the cut face of the peat mass. Accordingly:

- free faces should be inspected for evidence of instability (cracking, bulging, excessive discharge of water or sudden cessation in discharge); and

- where significant depths of peat are to be stored adjacent to an excavation, stability analysis should be conducted to determine Factor of Safety (FoS) and an acceptable FoS adopted for loaded areas.

As with floating tracks, regular routine monitoring should be scheduled post-construction to ensure that hydrological pathways and track integrity have been suitably maintained.

4.5 Cable Trenches

Cable trenches either require peat excavation specifically for this purpose, or they can be constructed within landscaping of shoulders adjacent to floating tracks. Guidance[6] is as follows:

- utilise peat shoulders for cable lays where possible to minimise peat excavations specifically for this purpose, in this case, peat shoulders should be 1.0m to 1.5m thick;
- where cable trenching is constructed adjacent to a floating road, ensure the trench is backfilled to prevent void filling by material migration;
- minimise time between excavation of the cable trench and peat reinstatement, preferably avoiding excavation until the electrical contractor has cables onsite ready for installation; and
- avoid incorporating substrate materials in the excavation, to minimise contamination of the peat to be reinstated. Replace excavated materials sequentially.

4.6 Peat Excavation, Storage and Transport

Where peat is to be re-used or reinstated with the intention that its supported habitat continues to be viable, the following good practice outlined below applies.

4.6.1 Excavation

Excavated peat should be excavated as turves, including the acrotelm (surface vegetation) and a layer of adjoining catotelm (more humified peat) typically up to 500mm thick in total, or as blocks of catotelm; the acrotelm should not be separated from its underlying peat;

- the turves should be as large as possible to minimise desiccation during storage, though the practicalities of handling should be considered;
- contamination of excavated peat with substrate materials to be avoided at all times; and
- consider timing of excavation activities to avoid very wet weather and multiple handling to minimise the likelihood of excavated peat losing structural integrity.

If possible, extract intact full depth acrotelm layers from the top surface of the peat deposit. This technique will maintain connectivity between the surface vegetation and the partially decomposed upper layers of the catotelm.

4.6.2 Storage

The following good practice applies to the storage of peaty soils/peat:

- stripped materials should be carefully separated to keep peat and other soils apart;
- to minimised handling and haulage distances, excavated material should be stored local to the site of excavation or end point of restoration;
- peat turves should be stored in wet conditions or irrigated in order to prevent desiccation (once dried, peat will not rewet);

- stockpiling of peat should be in large volumes to minimise exposure to wind and sun (and desiccation), but with due consideration for slope stability, but should not exceed 1m in height to maintain stability of stockpile;
- stockpiles should be isolated from watercourses or drains with appropriate bunding to minimise pollution risks;
- excavated peat and topsoil stored separately, should be stored to a maximum of 1m thickness;
- stores of non-turf (catotelm) peat should be bladed off to reduce the surface area and desiccation of the stored peat; and
- peat storage areas should be monitoring during periods of very wet weather, or during snowmelt, to identify early signs of peat instability.

4.6.3 Temporary Storage

Any peaty soils/peat to be removed during construction would require a temporary storage area near to the construction works/area of re-use. Where peat cannot be transferred immediately to an appropriate restoration area, short term storage will be required. In this case, the following good practice applies:

- peat should be stored around the turbine perimeter at sufficient distance from the cut face to prevent overburden induced failure;
- local gullies, diffuse drainage lines (or very wet ground) and locally steep slopes should be avoided for peat storage; and
- drying of stored peat should be avoided by irrigation or by seeding (although this is unlikely to be significant for peat materials stored less than 2 months).

For crane pads, borrow pits and compounds (with longer term storage requirements), the following good practice applies:

- peat generated from crane pad locations should be transported directly to its allocated restoration location, to minimise the volume being stockpiled with the possibility of drying out;
- stores of catotelmic peat should be bladed off to reduce their surface area and minimise desiccation;
- where transport cannot be undertaken immediately, stored peat should be irrigated to limit drying and stored on a geotextile mat to promote stability; and
- monitoring of large areas of peat storage during wet weather or snowmelt should be undertaken to identify any early signs of peat instability.

4.6.4 Transport

The following good practice applies to transport:

- movement of turves should be kept to a minimum once excavated, and therefore it is preferable to transport peat planned for translocation and reinstatement to its destination at the time of excavation; and;
- if HGVs/dump trucks that are used for transporting non-peat material are also to be used for peat materials, measures should be taken to minimise cross-contamination of peat soils with other materials.

4.6.5 Handling

Following refinement of the wind farm peat model, a detailed storage and handling plan should be prepared as a detailed PMP forming part of the detailed CEMP, including:

- best estimate excavation volume at each infrastructure location (including peat volumes split into area/volume of 'acrotelm' or 'turf', and volume of catotelm) which would be achieved by undertaking additional probing in line with current guidance following removal of trees post-consent;
- volume to be stored locally and volume to be transferred directly on excavation to restoration areas elsewhere (e.g. disused quarries, borrow pits or forest drains) in order to minimise handling;
- location and size of storage area relative to turbine foundation, crane hardstanding and natural peat morphology / drainage features; and
- irrigation requirements and methods to minimise desiccation of excavated peat during short term storage.

These parameters are best determined post-consent in light of detailed ground investigation with the micro-siting areas for each element of infrastructure.

4.7 Restoration

During restoration, the following best practice should be followed:

- carefully evaluate potential restoration sites, such as borrow pits for their suitability, and agree that these sites are appropriate with the ECoW, landowners and relevant consultees;
- undertake restoration and revegetation or reseeding work as soon as possible;
- where required, consider exclusion of livestock from areas of the site undergoing restoration, to minimise impacts on revegetation; and
- as far as reasonably practicable, restoration should be carried out concurrently with construction rather than at its conclusion.

5.0 Site Based Peat Excavation and Management Assessment

This Stage 1 PMP has been undertaken as part of the EIA Report for the proposed development to ensure that there is an understanding of the extent of peat on Site, the total amount of peat that might be excavated, a demonstration that the current design avoids areas of deep peat where possible and that the reuse of the excavated materials is certain and minimised where possible, and in line with updated industry good practices and guidance.

The proposed development comprises 25 wind turbines and associated crane hardstandings, a single access point for construction traffic, on-site access tracks of cut and floating construction, temporary construction compounds and permanent substation compound with operations building and underground cabling.

Table 5-1: Excavation Materials Management Plan

Method	Volume of Excavated Material (m^3)	How much of this can be re-used on site (%)	Opportunity for Avoidance or Minimisation of Excavated Material	Re-use Requirements	Hierarchy Adherence	Limitations and Considerations
Access Track (Excavated) Total length of the excavated tracks would be 16.5km with an average peat depth of 0.55m.	58,384m^3	55%	The access track route has been subject to a number of design iterations to avoid deeper peat and steep slopes.	Verge restoration and visual screening, particularly along access track. Sections of the route may require cut and fill and these slopes would require restoration to minimise visual impact **39,552m^3** of excavated peat and peaty soil would be used along access tracks.	Avoidance was first level of screening to avoid areas of thicker peat. Routing has been planned on thinner peat or peaty soils where possible. The layout design has been guided by constraints which highlight ecological, hydrogeological and geomorphological - all of which identify the peat areas to avoid.	Requires detailed ground investigation to fully characterise peat. Detailed assessment may identify further lengths of floating access tracks, which would further reduce requirement for excavation.
Site Track (Existing/Upgrade) It is anticipated that 12.1km of existing tracks on-site would be upgraded.	26,795m^3	81%	Existing tracks have been utilised where possible to minimise the disturbance of the peat.	Verge restoration along access tracks **28,968m^3**	Avoidance was first level of screening to avoid areas of thicker peat. Routing has been planned to utilise existing tracks.	Requires detailed ground investigation to fully characterise peat. Detailed assessment may identify further lengths of floating access tracks, which would further reduce requirement for excavation.
Site Track (Floated) It is anticipated that 2.2km of floating tracks would be required, which	Not applicable	Not applicable	No excavated material except where cable trenches are proposed (see below).	Verge restoration along access tracks **5,328m^3**	Looked at different cut off depths for floating access track. Based on >1m depth.	Requires detailed ground investigation to fully characterise peat. Verge restoration must avoid impacting existing unexcavated peat.

Method	Volume of Excavated Material (m^3)	How much of this can be re-used on site (%)	Opportunity for Avoidance or Minimisation of Excavated Material	Re-use Requirements	Hierarchy Adherence	Limitations and Considerations
would generate no surplus peat.						
Turning Heads 25 No. have been proposed.	2,772m^3	81%	Tracks have been subject to several design iterations, to avoid thick peat where possible.	Verge restoration around turning heads **2,250m^3**	Avoidance was first level of screening to avoid areas of thicker peat.	Requires detailed ground investigation to fully characterise peat.
Turbine Foundations 25 No. turbines with average excavation of 30m diameter and 0.4m thickness of peat.	7,065m^3	17%	Turbine locations have been subject to a number of design iterations to avoid thicker peat and steep slopes.	At turbine foundations topsoil would be stripped keeping top 200mm of turf intact. This would be stored adjacent to the base working area and would be limited to 0.5m height. 1,178m^3	Avoided areas of thick peat for turbine bases where possible to minimise removal of excessive materials.	Requires detailed ground investigation to fully characterise peat.
Permanent Crane Pad/Hardstanding 25 No. with an average excavation area of 1,896m^2. 0.56m thickness of peat at crane pad/hardstanding locations.	26,600m^3	7%	Hardstanding locations have been influenced by the turbine design iterations to avoid thicker peat and steep slopes.	At crane hardstandings topsoil would be stripped keeping top 200mm of turf intact. This would be stored adjacent to the base working area and would be limited to 0.5m height. 1,750m^3	Avoided areas of thick peat for turbine bases to minimise removal of excessive materials. Orientation of crane hardstandings to be designed following detailed ground investigation, to avoid constraints and minimise requirement for peat excavation.	Requires detailed ground investigation to fully characterise peat.

Method	Volume of Excavated Material (m^3)	How much of this can be re-used on site (%)	Opportunity for Avoidance or Minimisation of Excavated Material	Re-use Requirements	Hierarchy Adherence	Limitations and Considerations
Temporary Crane Pad/Hardstanding 25 No. with an average excavation area of 2,188m^2. 0.56m thickness of peat at crane pad/hardstanding locations.	30,800m^3	100%	Hardstanding locations have been influenced by the turbine design iterations to avoid thicker peat and steep slopes.	Materials would be re-used on site to reinstate working areas and for appropriate landscaping. 30,800m^3	Avoided areas of thick peat for turbine bases to minimise removal of excessive materials. Orientation of crane hardstandings to be designed following detailed ground investigation, to avoid constraints and minimise requirement for peat excavation.	Requires detailed ground investigation to fully characterise peat.
Substation compound with an approximate area of 1,050m^2 and 0.48m thickness of peat.	2,550m^3	7%	The proposed substation compound would largely be located on peaty/glacial soils adjacent to the proposed access tracks.	Materials would be re-used on site to reinstate working areas and for appropriate landscaping. 188m^3	Avoided siting substation on thick peat areas where possible.	Requires detailed ground investigation to fully characterise ground conditions.
Temporary Construction Compound North with an approximate area of 160m x 90m and 0.88m thickness of peat.	12,672m^3	100%	The proposed construction compound would largely be located on peaty/glacial soils adjacent to the proposed access tracks.	Materials would be re-used on site to reinstate working areas and for appropriate landscaping. 12,672m^3	Avoided siting Construction Compound on thick peat areas where possible.	Requires detailed ground investigation to fully characterise ground conditions.
Temporary Construction Compound South	5,796m^3	100%	The proposed construction compound would	Materials would be re-used on site to reinstate	Avoided siting Construction Compound on thick peat areas where possible.	Requires detailed ground investigation to fully characterise ground conditions.

Method	Volume of Excavated Material (m^3)	How much of this can be re-used on site (%)	Opportunity for Avoidance or Minimisation of Excavated Material	Re-use Requirements	Hierarchy Adherence	Limitations and Considerations
with an approximate area of 180m x 70m and 0.46m thickness of peat.			largely be located on peaty/glacial soils adjacent to the proposed access tracks.	working areas and for appropriate landscaping. 5,796m^3		
Borrow Pits There are 5 No. borrow pit options, generally with limited peat cover.	Borrow Pit 1: 3,109.92m^3 Borrow Pit 2: 2,156m^3 Borrow Pit 3: 6,395.76m^3 Borrow Pit 4: 251.55m^3 Borrow Pit 5: 13,594.50m^3	100%	There is limited peaty soils/peat overlying the selected borrow pits.	Limited peaty topsoil can be stockpiled and used for restoration. Peat/peaty soils from elsewhere on-site could be used to restore the proposed borrow pits with the following volumes: Borrow Pit 1: **10,032m^3** Borrow Pit 2: **8,624m^3** Borrow Pit 3: **22,842m^3** Borrow Pit 4: **8,385m^3** Borrow Pit 5: **27,189m^3**	Site selection avoided areas of peat for borrow pits, identified sites on bedrock or close to minimise removal of excessive materials.	Current calculations are based on conservative re-use and based on the use of all five borrow pits. Detailed ground investigation is required to assess the ground conditions at each site.
Total Excavated	194,942.13m^3		Total Re-use	205,553.00m^3		

Based on the values indicated, there is no surplus of peat – See **Annex A**. Should further ground investigation information become available, the figures would need to be re-calculated, the figures in the table are indicative only.

6.0 Peat Excavation Considerations

This section of the stage 1 PMP includes the method for dealing with peat which could potentially be classified as waste (only if the above volumes estimate significant quantities of catotelmic peat, which cannot be re-used).

Table 6-1 outlines where those materials that are likely to be generated on-site, they fall within the Waste Management Licensing (Scotland) Regulations 2011.

Based on the results presented in **Table 6-1**, it has been concluded that all of the materials to be excavated onsite would fall within the non-waste classification as most of the topsoil and peaty soils would be re-used on site. Based on a detailed probing exercise and visual inspection of the peat, it is predominantly amorphous and heavily degraded. There are some localised deposits of shallow peat that generally comprise fibrous to pseudo-fibrous layers, whilst areas of thicker peat are predominantly pseudo-fibrous to amorphous layers. Areas of deep peat have been avoided by design, where possible.

Table 6-1: Excavated Materials – Assessment of Suitability

Excavated Material	Indicative Volume on Site by % of total excavated soils	Is there a suitable use for material	Is the Material required for use on Site	Material Classified as Waste	Re-use Potential	Re-use on Site
Mineral Soil	25	Yes	Yes	Not classified as waste	Yes	Will be re-used in reinstatement of floated access track verges, cut and fill verges, road verges, side slopes and check drains. Peripheral embankments of turbine bases, crane hardstandings and restoration of borrow pits
Turf (Surface layer of vegetation and fibrous matt)	35	Yes	Yes	Not classified as waste	Yes	
Acrotelmic peat	35	Yes	Yes	Not classified as waste	Yes	Will be re-used in reinstatement of floated access track verges, cut and fill verges, road verges, side slopes and check drains. Peripheral embankments of turbine bases, crane hardstandings and restoration of borrow pits.
Catotelmic Peat (amorphous material unable to stand unsupported when stockpiled >1m)	5 Very limited as it has been avoided by design.	Potentially	Potentially *	Potentially if not required as justifiable restoration of habitat management works	Limited	If peat does not require treatment prior to re-use it can be used on site providing adequate justification and method statements are provided and approved by SEPA. If it is unsuitable for use without treatment then it may be regarded as a waste. However every attempt to avoid this type of peat has been incorporated into the design.

*Such uses for this type of material are limited, however there may be justification for use in the base of borrow pits to maintain waterlogged conditions and prevent desiccation of restored area and in some habitat management works such as gully or ditch blocking where saturated peat is required to mimic mire type habitats and encourage establishment of sphagnum.

7.0 Conclusion

This Stage 1 PMP presents a pre-construction assessment of the expected peat extraction and reuse volumes associated with the works phase of the construction of the Site.

The figures detailed within this report are to be considered indicative at this stage. The total peat volumes are based on a series of assumptions for the layout of the proposed development and peat depth data averaged across discrete areas of the Site. Such parameters can still vary over small scale areas and therefore topographic changes in the bedrock profile could impact the total accuracy of the volume calculations. The accuracy of these predictions would be improved and updated with the results of further detailed peat probing data, to be carried out during refinement in accordance with 2017 guidelines, as part of detailed ground investigation to be undertaken post-consent. The figures shown in the tables suggest that the volumes of peat excavated on-site would not create a surplus.

The Site supports peat that is generally heavily decomposed peat with very little plant structure, there are some localised deposits of shallow peat that generally comprise fibrous to pseudo-fibrous layers, whilst areas of thicker peat are predominantly pseudo-fibrous to amorphous layers. Good practice standards, which will be outlined in the updated CEMP, relating to excavation, handling and storage of peat, shall ensure against any compromise to the structural integrity of the peat and its associated suitability for reuse. Avoidance of localised pockets of deep peat that would otherwise require excavation will continue to be a key design refinement objective. Furthermore, it is expected that such micrositing onto land supporting shallower peat deposits shall be possible during the works.

Post-consent, the Stage 1 PMP and the Outline CEMP would be updated with information obtained during detailed ground investigations and design stage. These plans would be developed to update the Outline CEMP, with post-construction restoration plans. This would be reviewed and monitored along with the updated PMP and CEMP to ensure compliance with method statements and to keep track of volumes.
